

# Neutrons and X-rays

An aerial photograph of the Diamond Light Source facility. The central feature is a large, circular, white-roofed building, likely the synchrotron itself. Surrounding it are numerous other buildings of various sizes and colors, including brick and concrete structures. There are several parking lots filled with cars. The facility is situated in a green, rural area with fields and trees. The overall scene is a complex of industrial and research buildings.

# X-ray – matter interactions

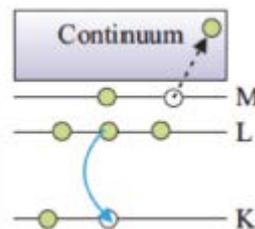

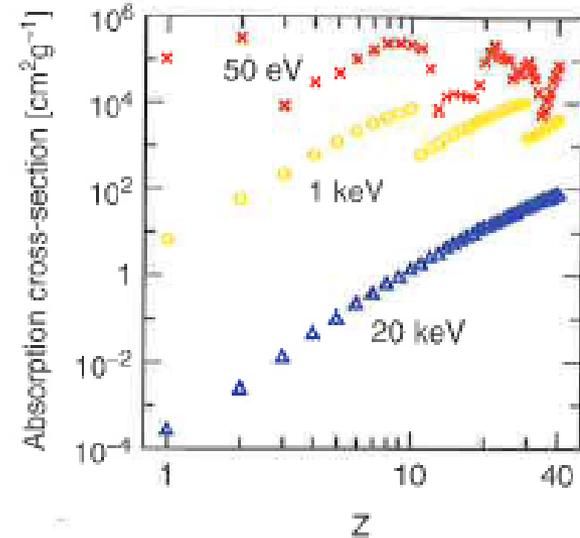

# X-ray absorption/emission processes

**Photo-electric absorption**

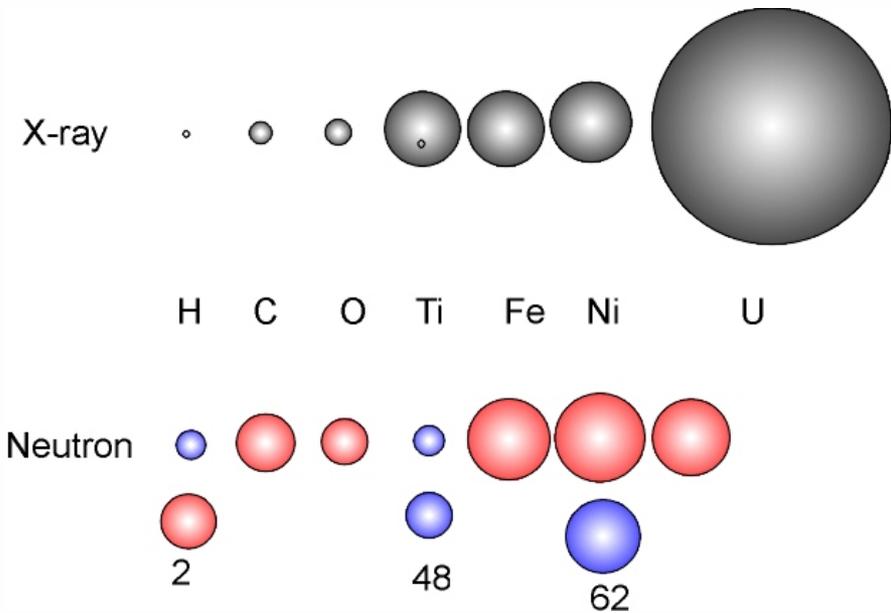

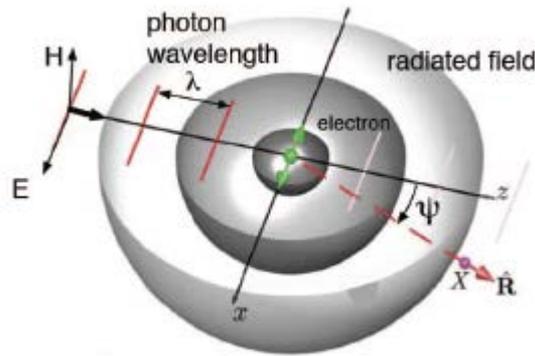

**Fluorescent emission**

**Auger electron emission**

# X-ray scattering - elastic

- Leading term is the (Thomson) scattering by electrons
  - The electric field of the incident EM wave drives motion of the electrons and produces spherical waves of the same energy which may interfere to produce a diffraction pattern
  - Elastic scattering intensity is proportional to  $Z^2$

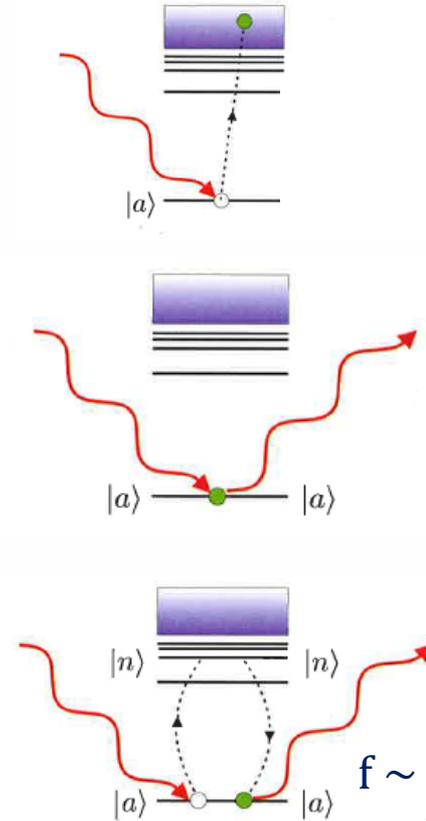

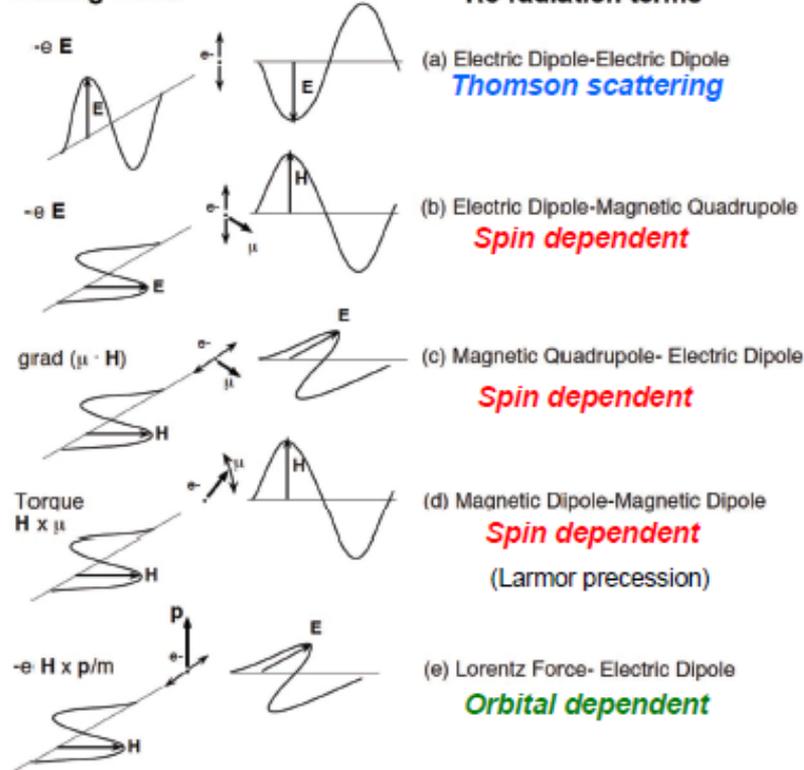

# X-ray scattering - elastic

- Secondary terms are weaker
  - Various (non-resonant) magnetic terms  $10^5 - 10^7$  x weaker
  - If the energy of the incident photons is tuned to resonate with (virtual) transitions to intermediate states very strong amplification of the photon scattering process may occur (see later for RIXS too)

# Origins of diffraction at atomic scales

$$n\lambda = 2d \cdot \sin\theta$$

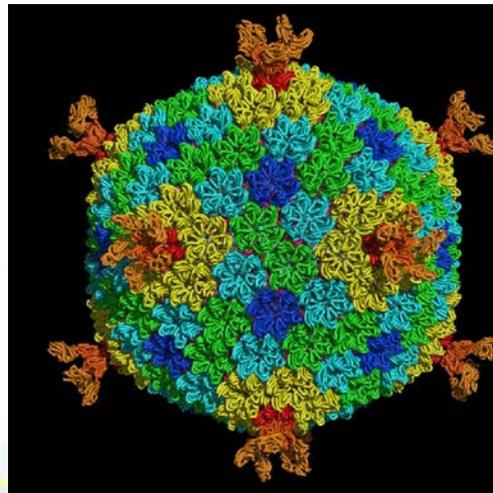

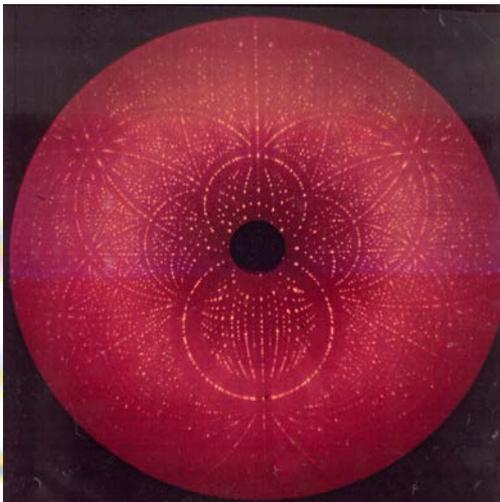

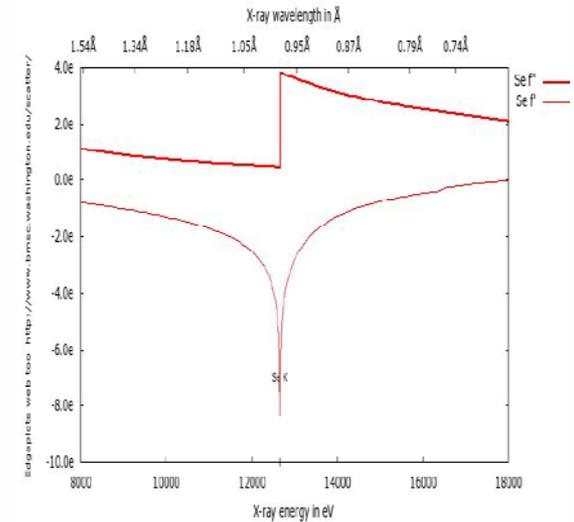

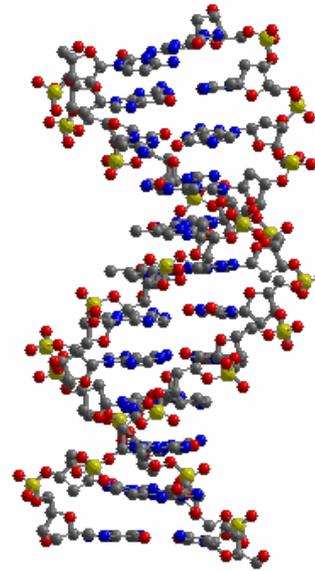

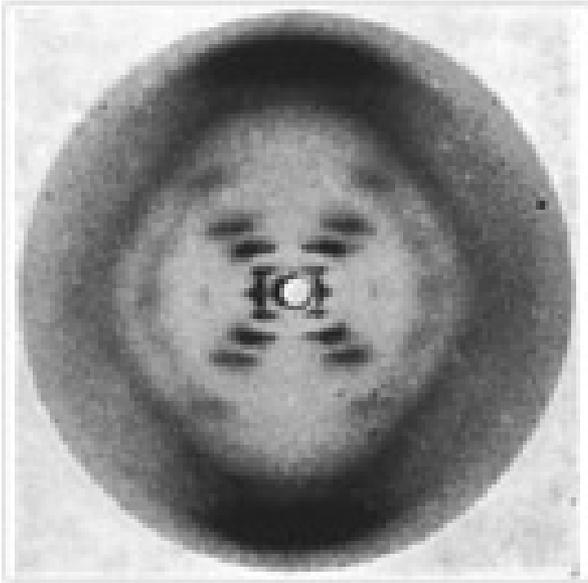

# 40 years on...

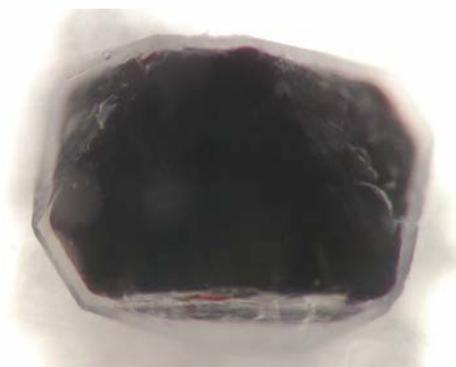

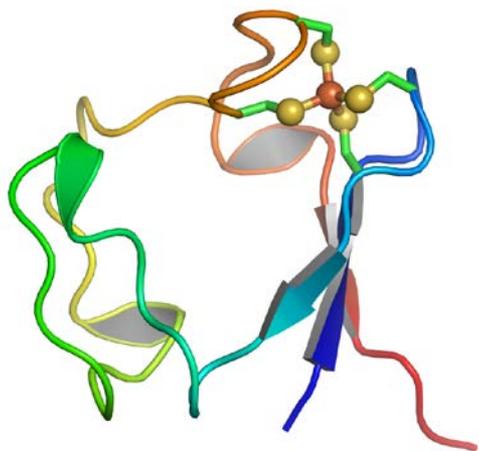

# Macromolecular crystallography today

- Brilliance and tunability of photon energy, high-performance computing –  $> 10^{10}$  times more information/second

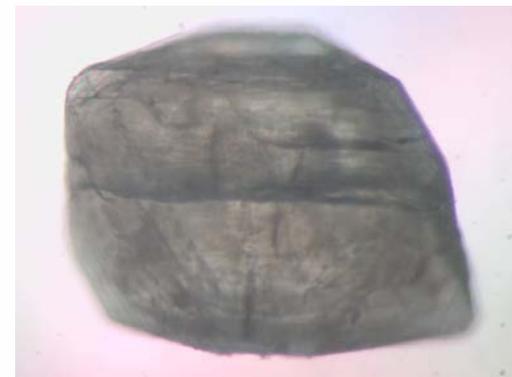

# Complementarity: neutrons

- Location of H atoms when X-rays/chemical 'rules' don't help
- Study of samples susceptible to radiation damage
- Study of Rubredoxin structure illustrates both
  - *Small (~6kD) iron-sulphur containing redox protein – important model system to understand electron transfer processes using redox systems – here  $Fe^{3+} - Fe^{2+}$*
  - *$Fe^{3+}$  form very easily reduced in the X-ray beam*

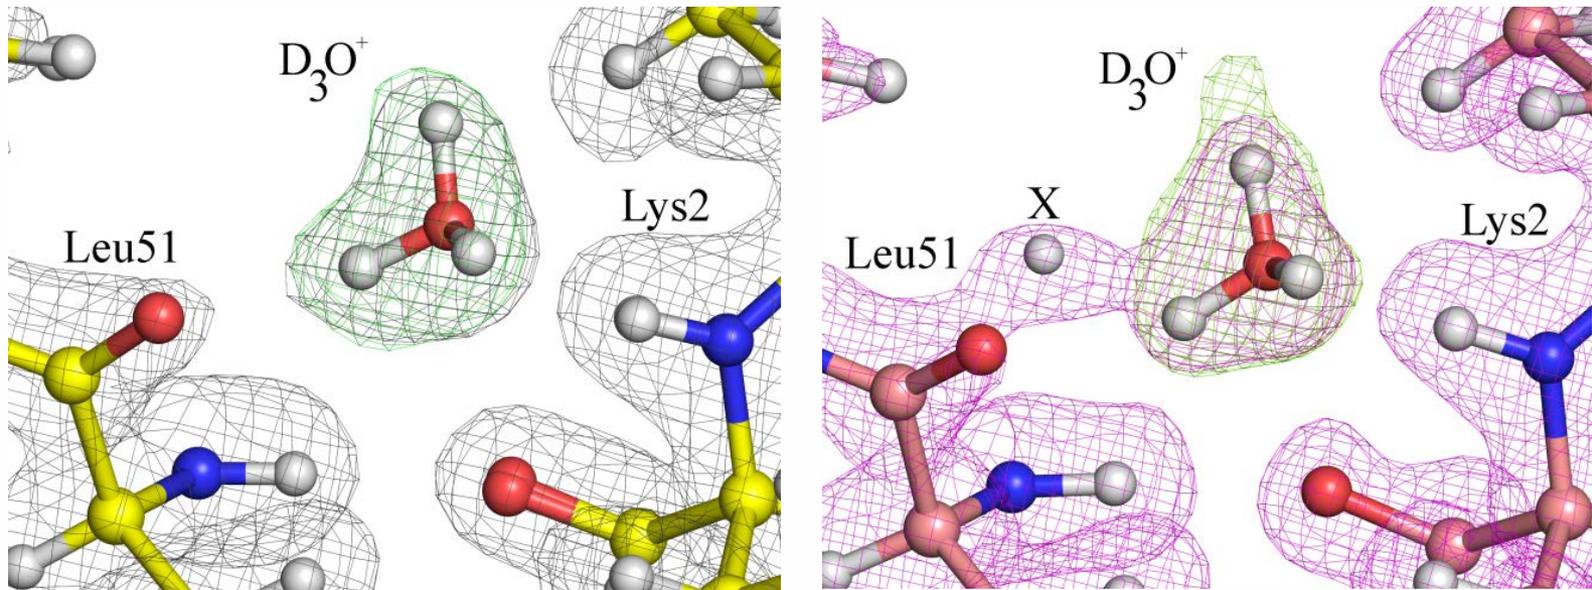

$Fe^{3+}$

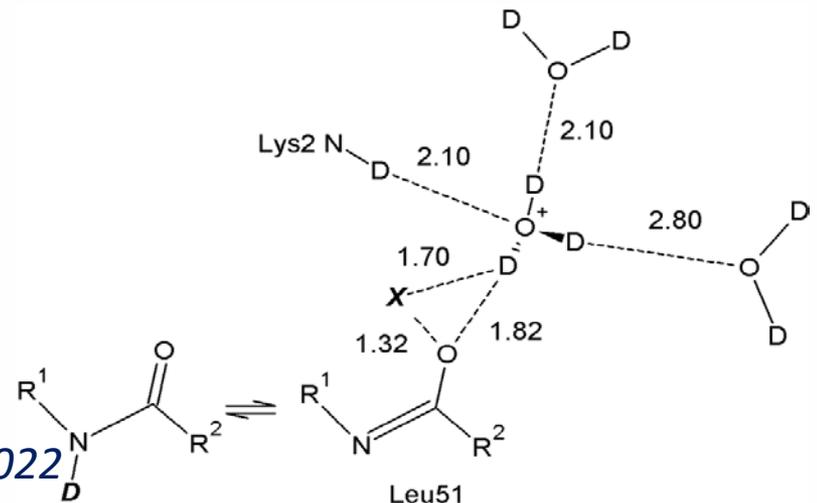

$Fe^{2+}$

# Complementarity: neutrons

- Structure of reduced and oxidised form measured on D19 at ILL

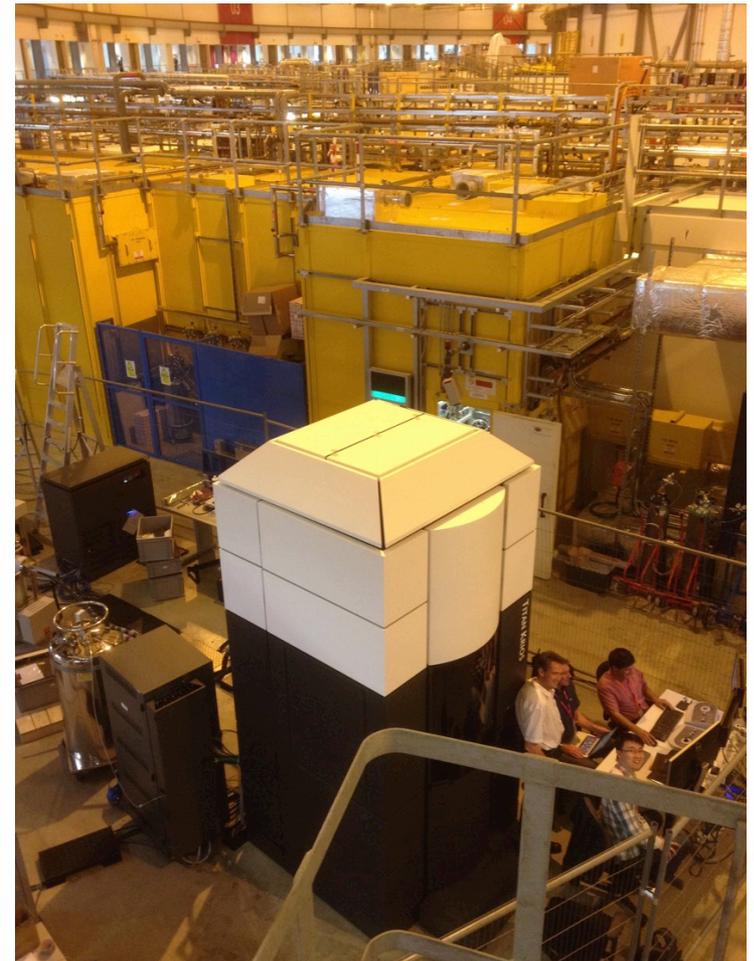

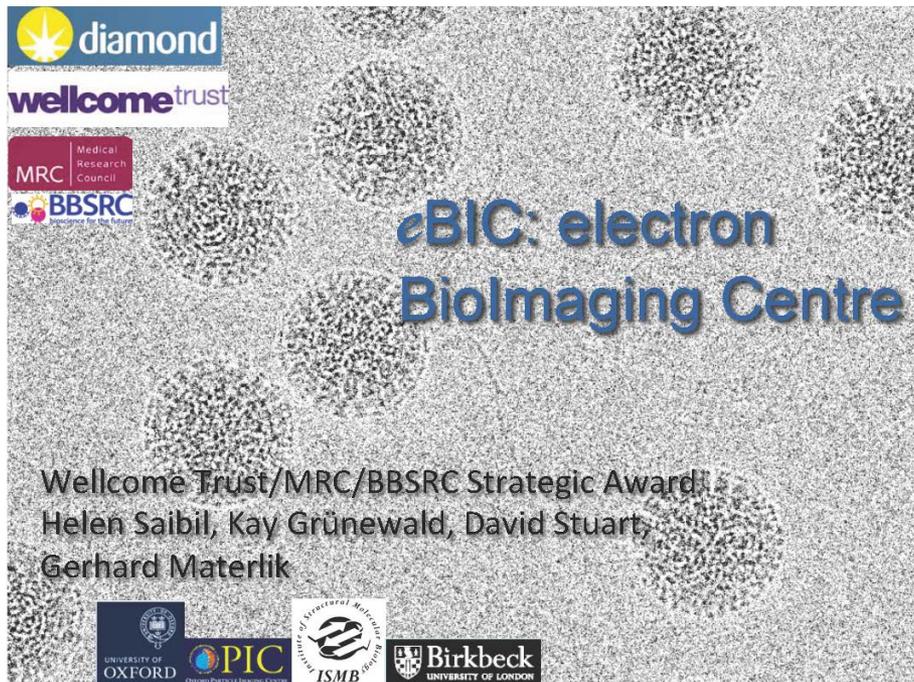

Observation of hydronium (D) ions and of tautomeric shifts following the change from the oxidised form to the reduced form

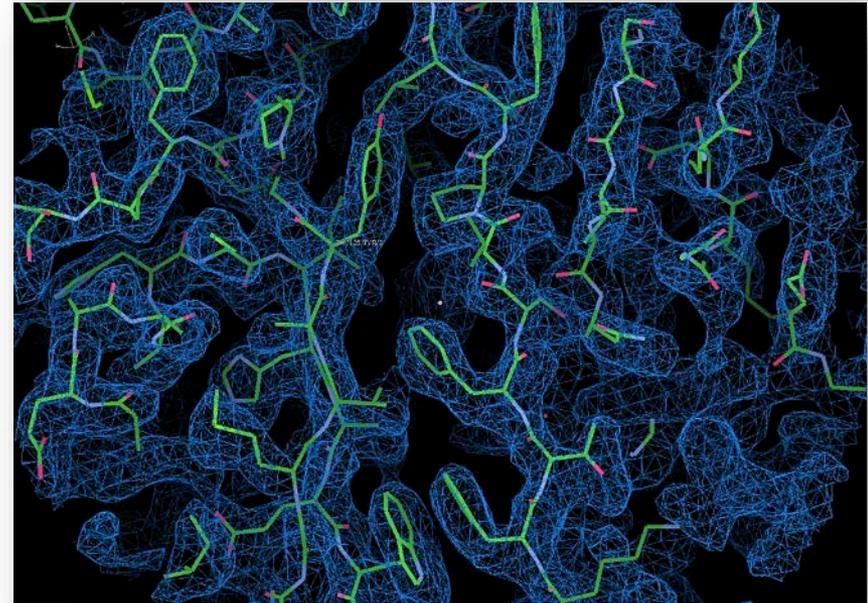

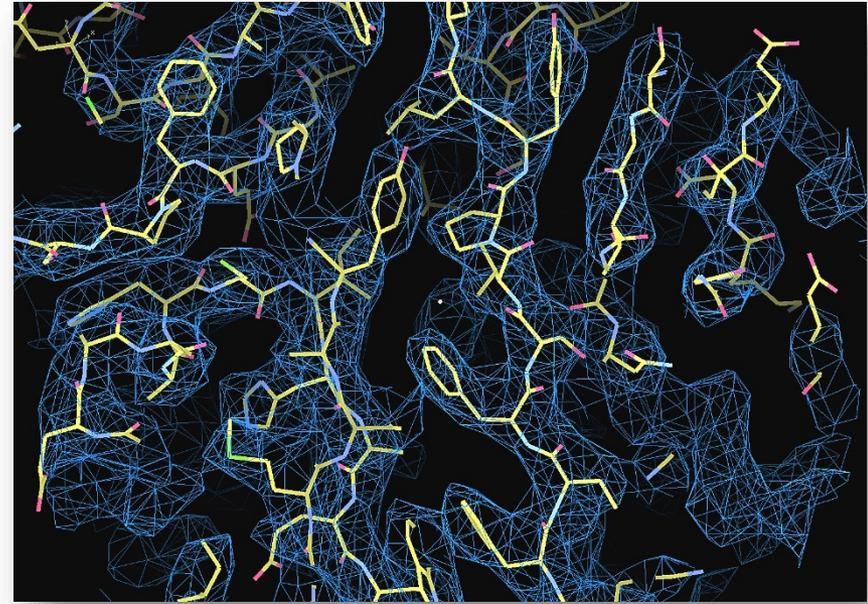

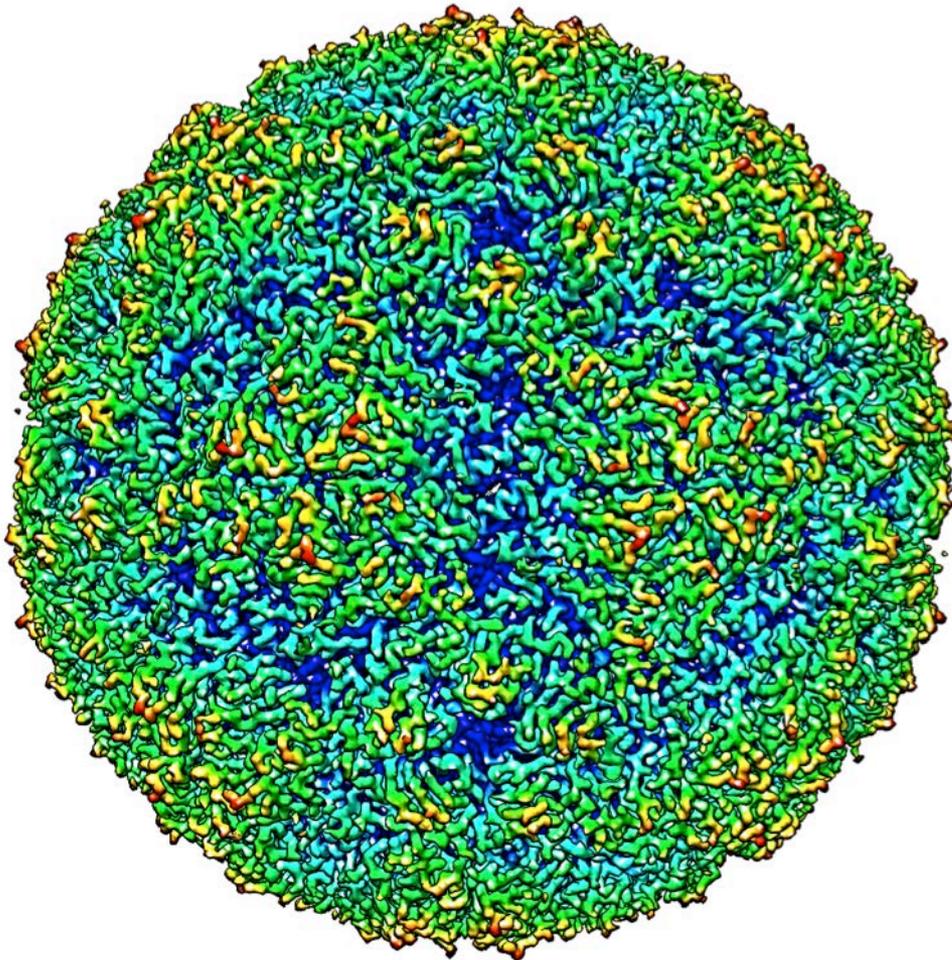

# Complementarity: the EM revolution

- Wonderful new detectors that collect movies and allow particle movements to be tracked in software to reveal atomic detail
- Native particles frozen in a water 'glass'

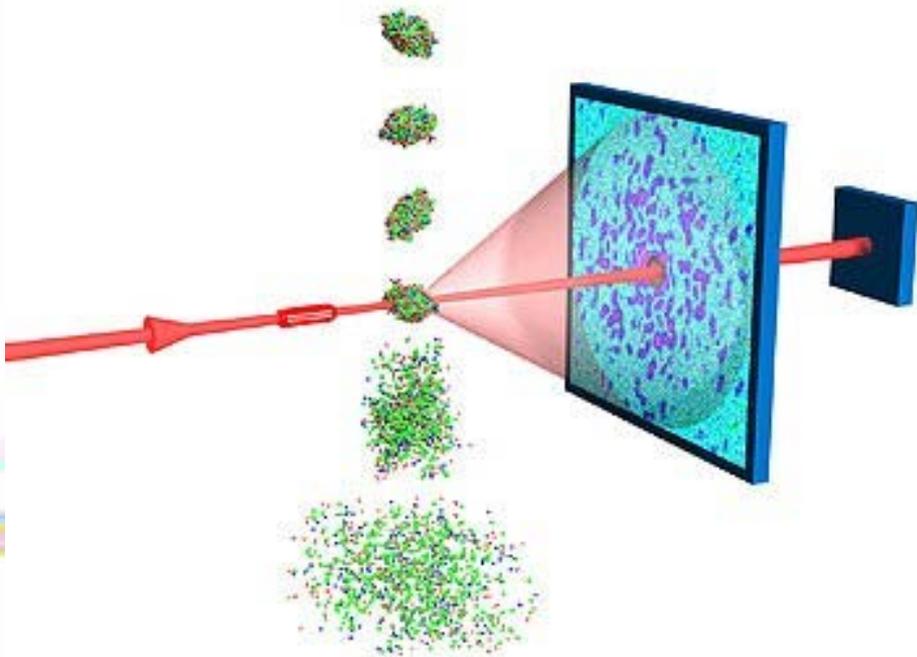

# Complementarity: the EM revolution

- Example from foot-and-mouth disease virus by electron microscopy and synchrotron X-rays

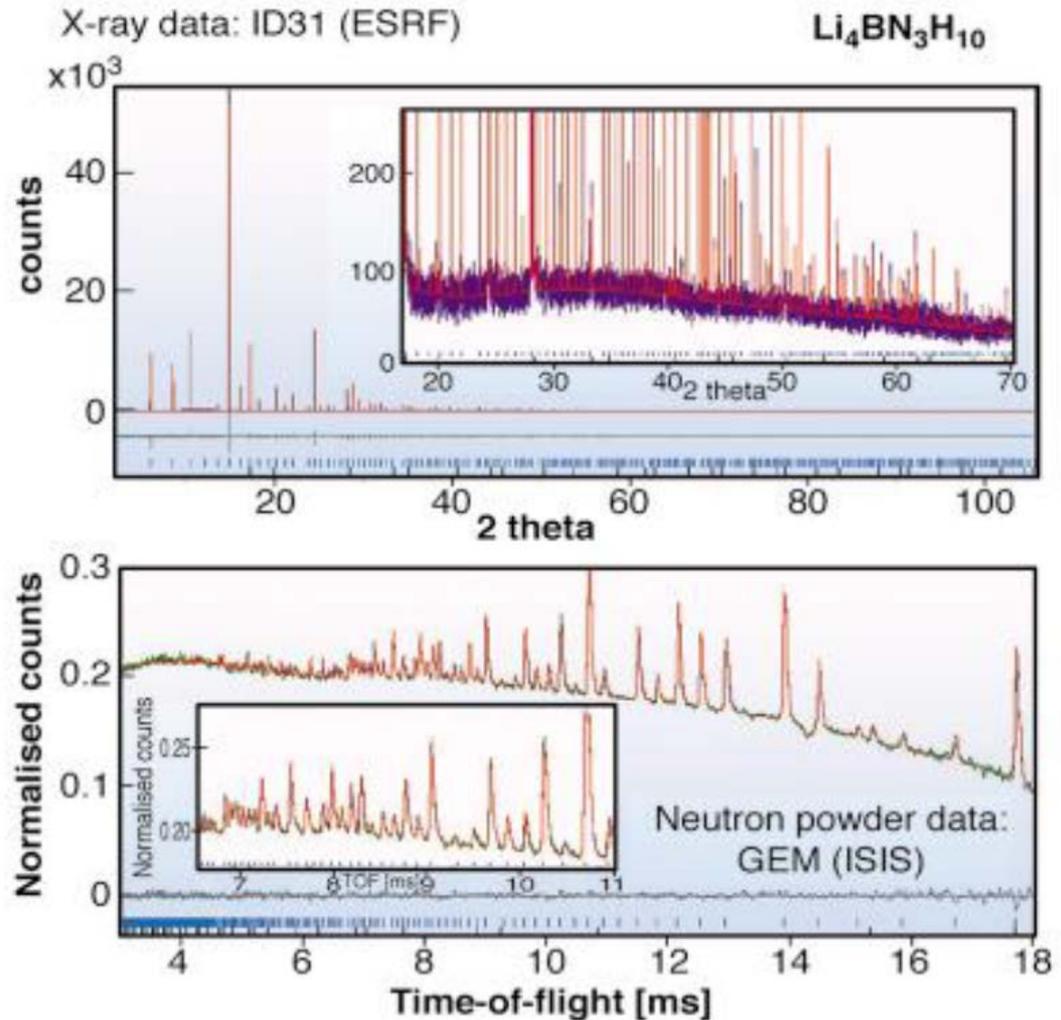

# Complementarity: FELs

- X-rays pulses in a free electron laser (FEL) are ultrafast (fs) and ultrabright ( $\times 10^{10}$ ) and capture structure before the sample is perturbed by the beam – ‘diffract and destroy’ !
- Challenge of sample injection, image processing...

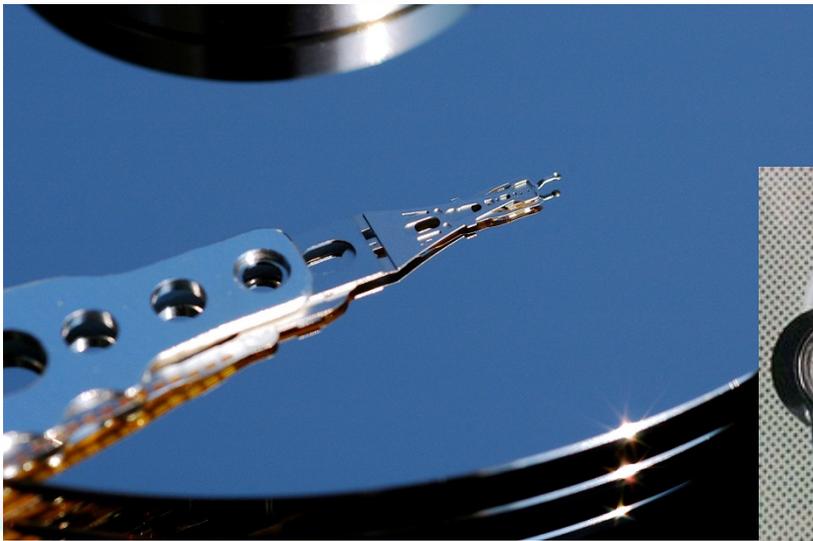

# 'Hard' materials

- Many important materials contain hydrogen or other light atoms that are crucial to function – e.g. for hydrogen storage
- Combine X-rays for rapid, high-resolution survey/ study then neutrons to locate H, Li, etc....

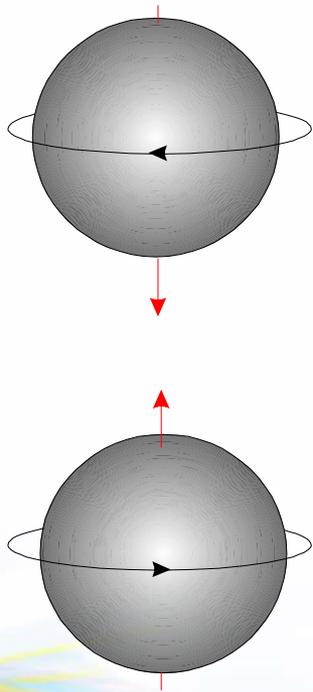

# Magnetic structures

- Need to measure magnetic (spin) structures and excitations at an atomic level to understand and predict magnetic properties
- Important for a wide range of functional materials for sensors, actuators, information storage, nanomedicine, superconductors...

# Magnetic structures: neutrons

- Scattering cross-section relatively simple and comparable in size to the nuclear cross-section

PHYSICAL REVIEW VOLUME 70, NUMBER 4 OCTOBER 13, 1949

### Detection of Antiferromagnetism by Neutron Diffraction\*

C. G. SHULL

Oak Ridge National Laboratory, Oak Ridge, Tennessee

AND

J. SAMUEL SMART

Naval Ordnance Laboratory, White Oak, Silver Spring, Maryland

August 29, 1949

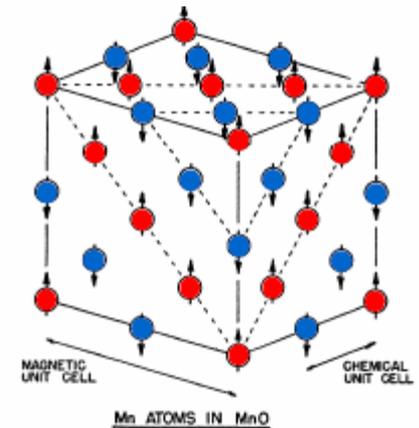

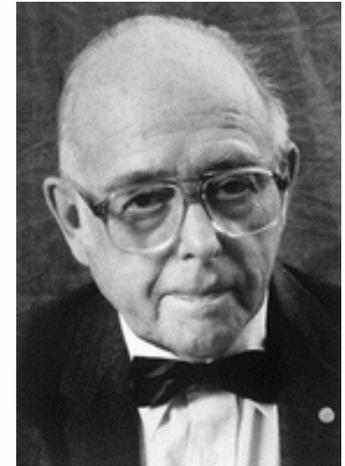

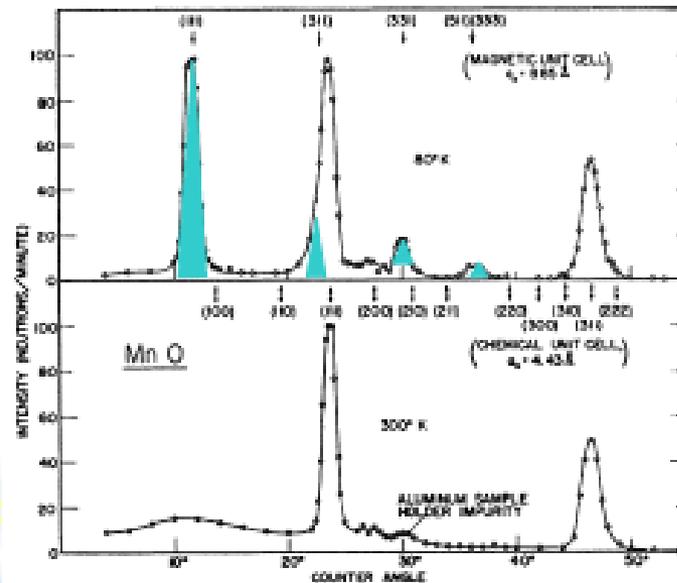

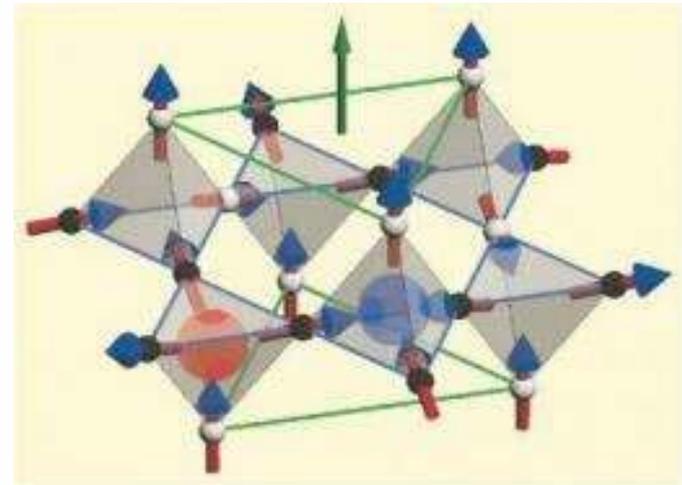

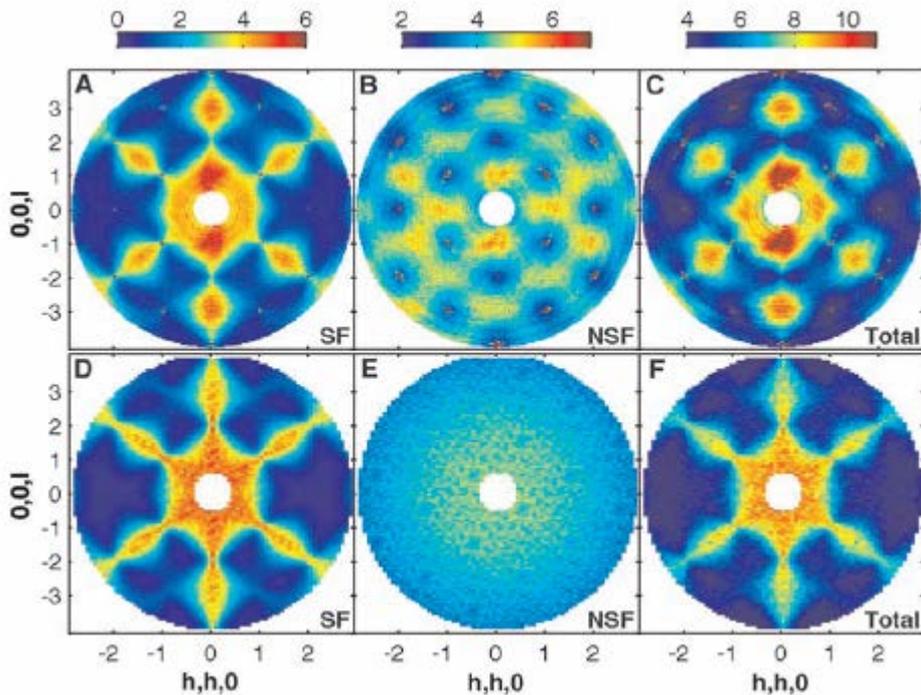

FIG. 1. Neutron diffraction patterns for MnO at room temperature and at 80°K.

# Magnetic structures: neutrons

- Polarisation techniques can provide all details of spin structure (zero-field polarimetry) and map out diffuse scattering from short-range order
- Penetrating ability of neutrons enables design of sophisticated sample environment and cryogenics to nK, *but* large samples are required

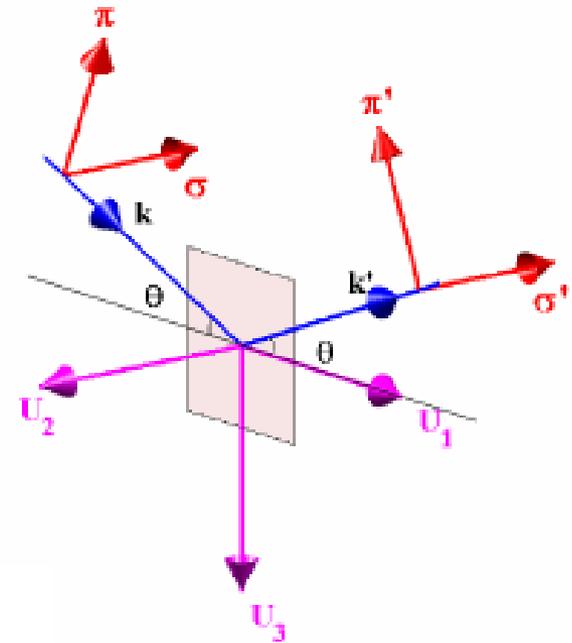

# Magnetic structures: X-rays

- Scattering cross-section generally very weak – typically  $10^6$  weaker than the nuclear (Thomson) terms ( $(\hbar\omega/mc^2) \sim 10^{-2} \rightarrow |f^{\text{mag}}/|f^{\text{at}}| \sim 10^{-6}$ )
- Polarisation analysis can be used to separate spin (S) and orbital (L) contributions
- Magnetic scattering amplitude  $f^{\text{mag}}(\mathbf{Q})$ :

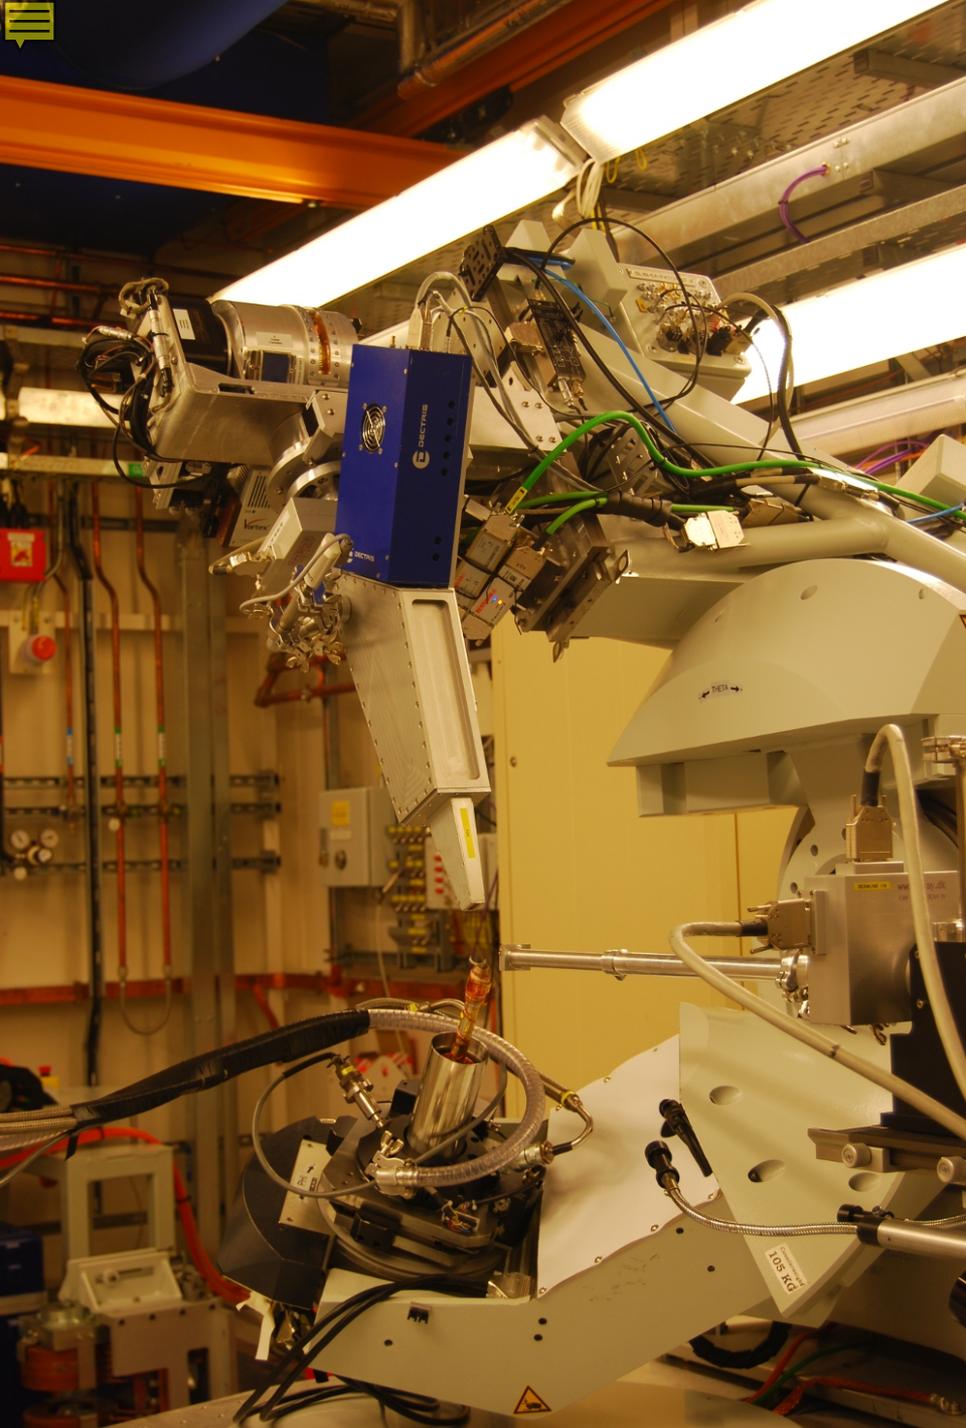

$$f^{\text{mag}}(\mathbf{Q}) = ir_0 \left( \frac{\hbar\omega}{mc^2} \right) \left[ \frac{1}{2} A'' \cdot L(\mathbf{Q}) + B \cdot S(\mathbf{Q}) \right]$$

$L(\mathbf{Q})$  and  $S(\mathbf{Q})$  are the Fourier transforms of the atomic and spin magnetisation densities;  $A''$  and  $B$  depend on the relative orientation of  $\mathbf{k}$ ,  $\mathbf{k}'$ ,  $\boldsymbol{\varepsilon}$ ,  $\boldsymbol{\varepsilon}'$

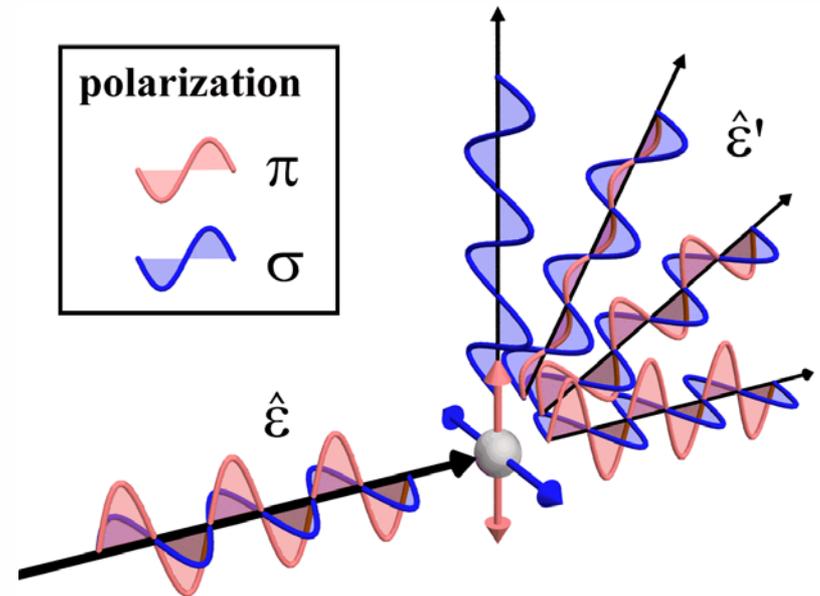

$$f^{\text{mag}}(\mathbf{Q}) = ir_0 \left( \frac{\hbar\omega}{mc^2} \right) \times$$

	$\hat{\boldsymbol{\varepsilon}}_{\perp} \equiv \boldsymbol{\sigma}$	$\hat{\boldsymbol{\varepsilon}}_{\parallel} \equiv \boldsymbol{\pi}$
$\hat{\boldsymbol{\varepsilon}}'_{\perp}$	$\sin 2\theta S_2$	$-2 \sin^2 \theta [(L_1 + S_1) \cos \theta - S_3 \sin \theta]$
$\hat{\boldsymbol{\varepsilon}}'_{\parallel}$	$2 \sin^2 \theta [(L_1 + S_1) \cos \theta - S_3 \sin \theta]$	$\sin 2\theta [2 \sin^2 \theta L_2 + S_2]$

- Versatile diffractometer: polarisation analysis and azimuthal angle
- Energy tunable from 1-15 keV to get good atomic resolution

# Magnetic structures: X-rays

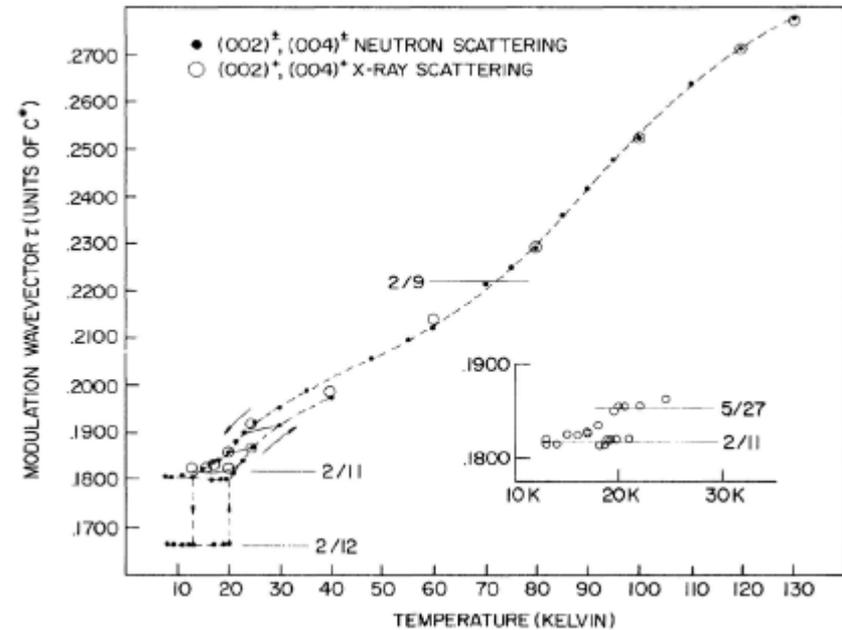

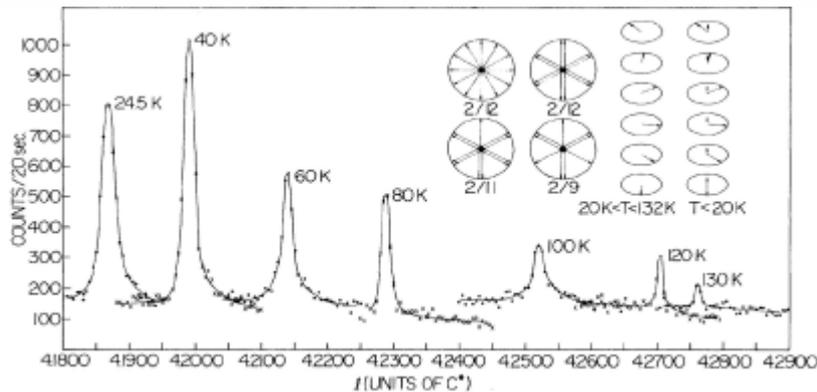

- First magnetic structures studied at a synchrotron in 1985 - spiral spin structure of Ho mapped out as a function of temperature

VOLUME 55, NUMBER 2      PHYSICAL REVIEW LETTERS      8 JULY 1985

## Magnetic X-Ray Scattering Studies of Holmium Using Synchrotron Radiation

Dixon Gibbs, D. P. Moncton, K. I. D'Aquila, J. Rabe (a) and R. H. Grigg (b)  
Department of Physics, Brookhaven National Laboratory, Upton, New York 11973  
(Received 26 March 1985)

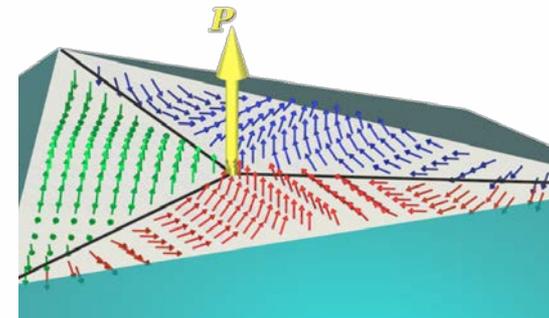

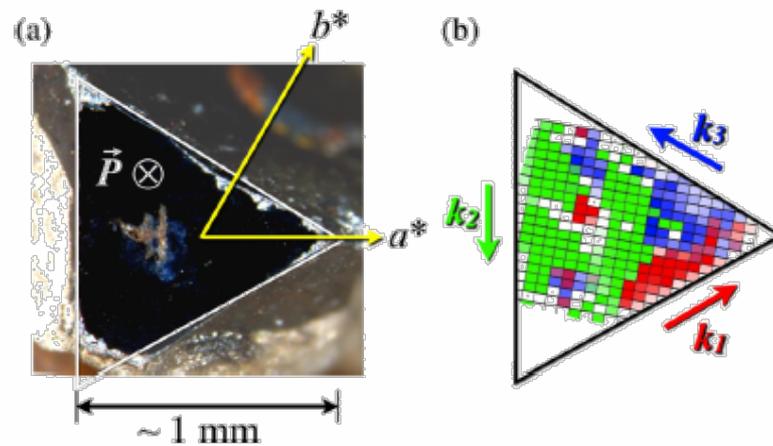

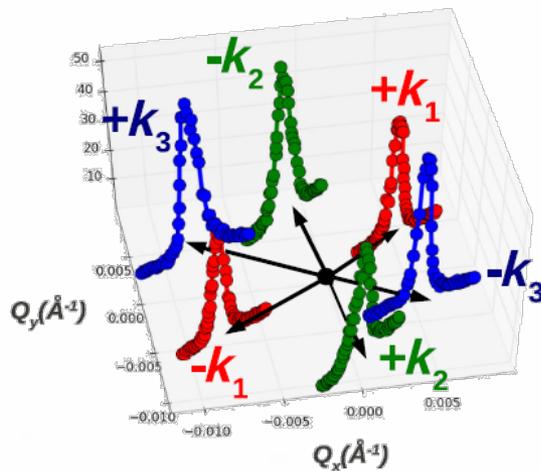

(1985) First Synchrotron Radiation Studies of Magnetism

- Advantages of (non-resonant) X-ray magnetic scattering
  - Orbital and spin magnetisation density may be separated
  - Highly-focused beams enable very small samples to be studied
  - High resolution in Q – e.g. for subtle changes in spin structure
  - **However**, cryogenics are challenging !

# Magnetic structures: X-rays

- $\text{BiFeO}_3$  has room-temperature coupling between magnetic and ferroelectric (FE) order.
- Map domain distribution with 50  $\mu\text{m}$  spot (LD) then probe helicity by CD: same helicity for single FE domain

## X-Ray Imaging and Multiferroic Coupling of Cycloidal Magnetic Domains in Ferroelectric Monodomain $\text{BiFeO}_3$

R. D. Johnson,<sup>1,2,\*</sup> P. Barone,<sup>3</sup> A. Bombardi,<sup>4</sup> R. J. Bean,<sup>5</sup> S. Picozzi,<sup>3</sup> P. G. Radaelli,<sup>1</sup>  
Y. S. Oh,<sup>6</sup> S.-W. Cheong,<sup>6</sup> and L. C. Chapon<sup>7</sup>

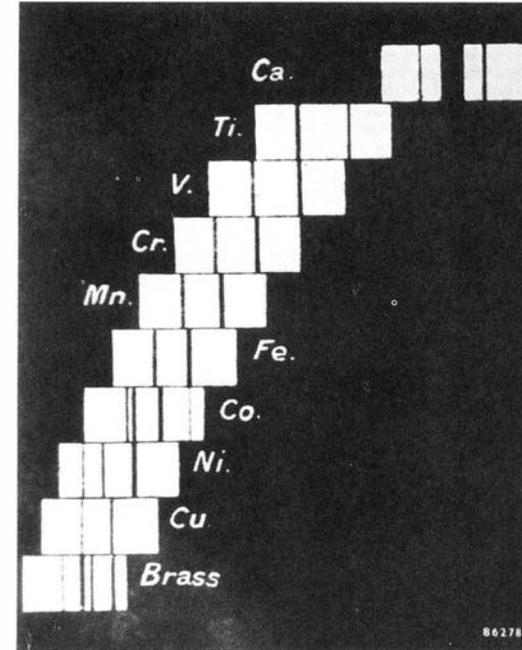

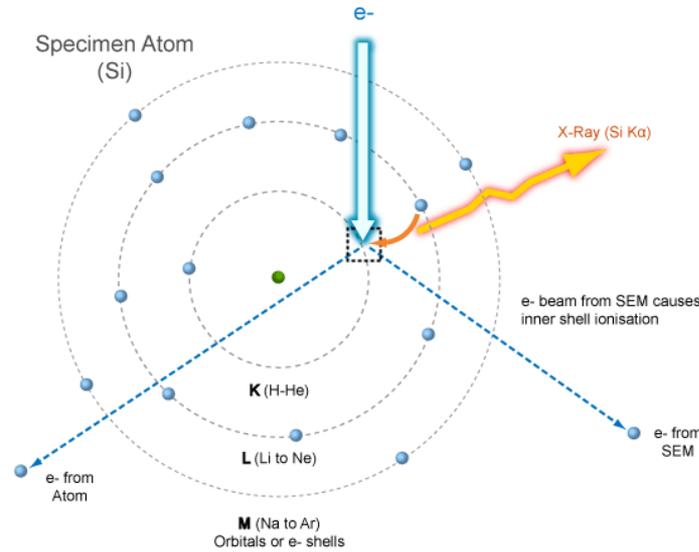

# Magnetic structures: resonant scattering

- Tune energy to a core-(empty) valence state transition and exploit resonant scattering to greatly enhance intensity ( $\times 10^3$ )
  - Sensitive to specific element and oxidation state
  - Dipole transitions ( $\Delta L = 1$ ) generally stronger than quadrupole transitions ( $\Delta L = 2$ ) and these will also be polarisation dependent; transitions from s to d or p states generally weaker because of lower overlap of wavefunctions
  - Sensitive to spin (S) though spin-orbit coupling
  - However, mostly limited to softer X-rays so will not give atomic resolution – tend to use for larger-scale structures (unit cell, periodic structures)

elements	edge	transition	energy range [keV]	resonance strength	comment
3d	K	1s → 4p	5 - 9	weak	small overlap
3d	L <sub>I</sub>	2s → 3d	0.5 - 1.2	weak	small overlap
3d	L <sub>II</sub> , L <sub>III</sub>	2p → 3d	0.4 - 1.0	strong	dipolar, large overlap, high spin polarisation of 3d
4f	K	1s → 5p	40 - 63	weak	small overlap
4f	L <sub>I</sub>	2s → 5d	6.5 - 11	weak	small overlap
4f	L <sub>II</sub> , L <sub>III</sub>	2p → 5d 2p → 4f	6 - 10	medium	dipolar quadrupolar
4f	M <sub>I</sub>	3s → 5p	1.4 - 2.5	weak	small overlap
4f	M <sub>II</sub> , M <sub>III</sub>	3p → 5d 3p → 4f	1.3 - 2.2	medium to strong	dipolar quadrupolar
4f	M <sub>IV</sub> , M <sub>V</sub>	3d → 4f	0.9 - 1.6	strong	dipolar, large overlap, high spin polarisation of 4f
5f	M <sub>IV</sub> , M <sub>II</sub>	3d → 5f	3.3 - 3.9	strong	dipolar, large overlap, high spin polarisation of 5f

Species identification

XRF tomography –  
Mo (green) and Pt (red)

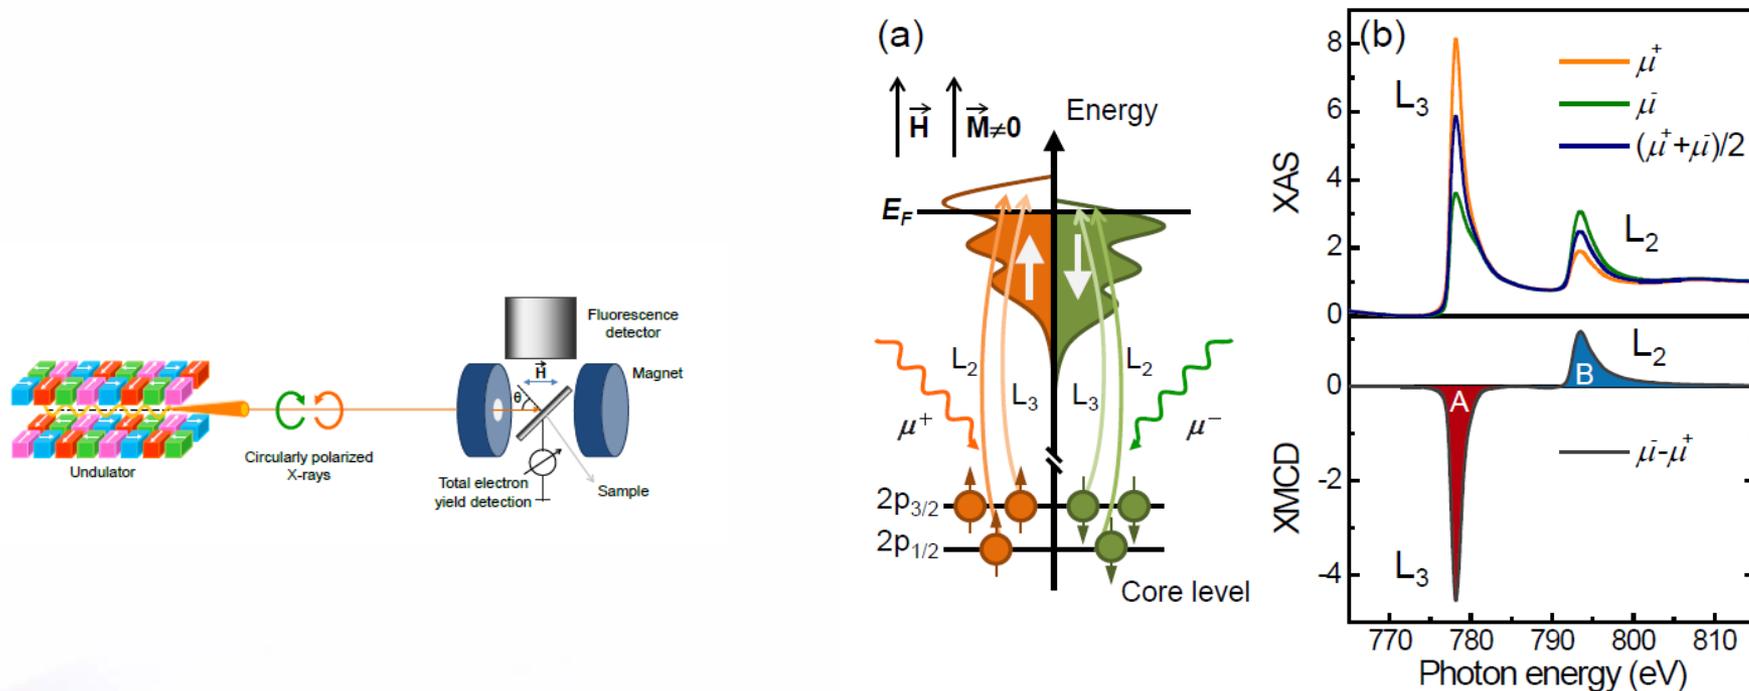

Species distribution

# XAS plus magnetic polarisation

- XAS with circularly polarised (CP) light: LCP-RCP probes polarisation of spin states by selectively exciting transitions with  $\Delta m = +/- 1 \rightarrow$  XMCD

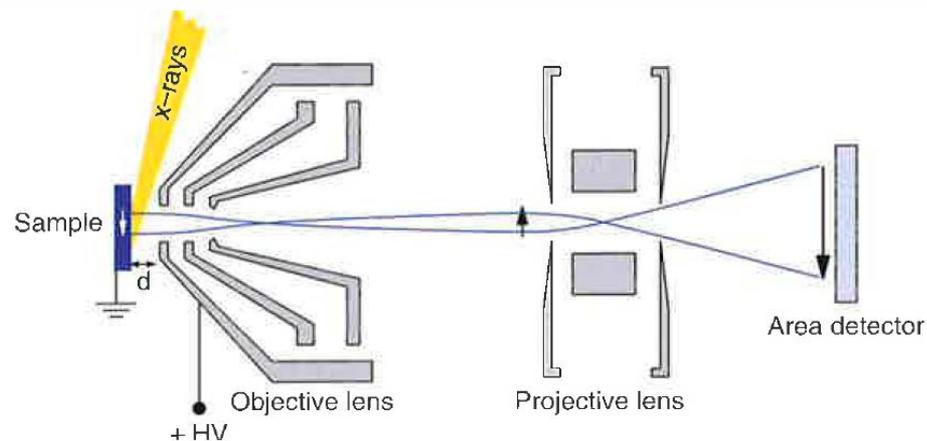

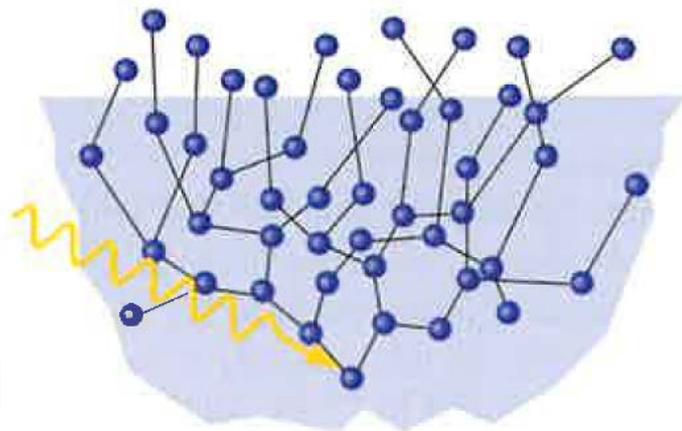

- XAS with LP radiation:  $\Delta (\perp - //) \sim \langle M^2 \rangle \rightarrow$  XMLCD

*G van der Laan and A.I. Figueroa,  
Coord. Chem. Reviews 277-278 (2014) 95*

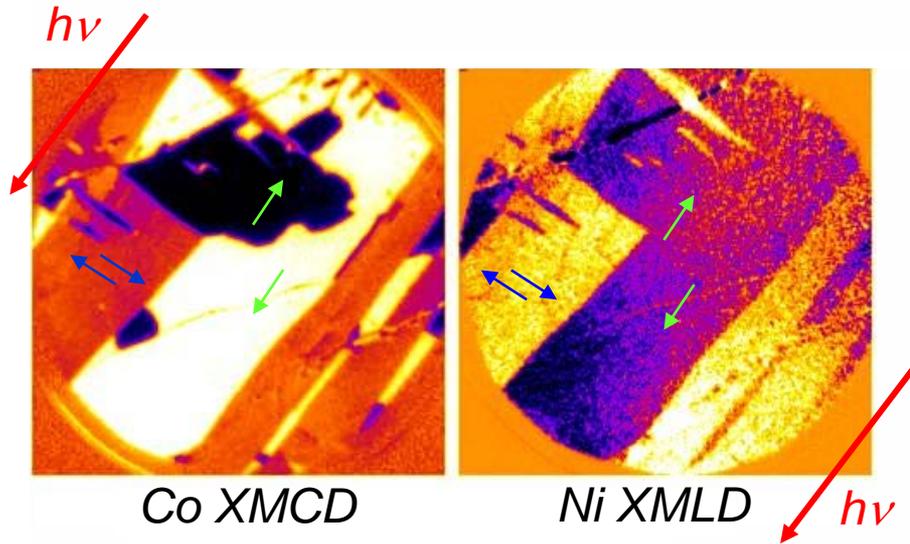

# Mapping nanomagnetism

- Resolution to 50 nm with Photoemission Electron Microscopy (PEEM)
- XAS in XANES region produces photoelectrons which create secondary, low-energy (eV) photoelectrons with longer mean-free path. Spatial resolution for imaging these  $e^-$  is 10's of nm

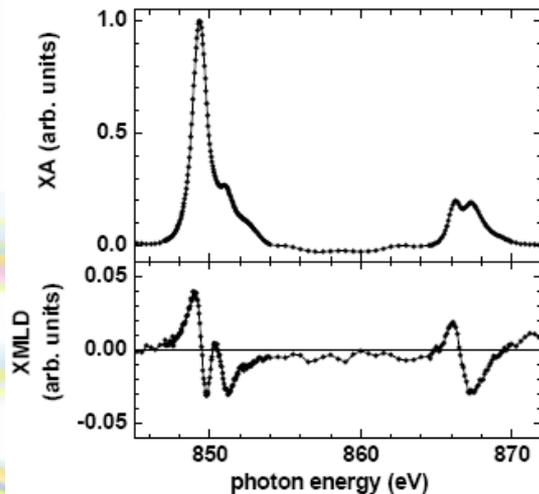

# Mapping nanomagnetism

- PEEM in combination with XMCD, XMLD to map domains to nm lengthscales

Co XMCD

Ni XMLD

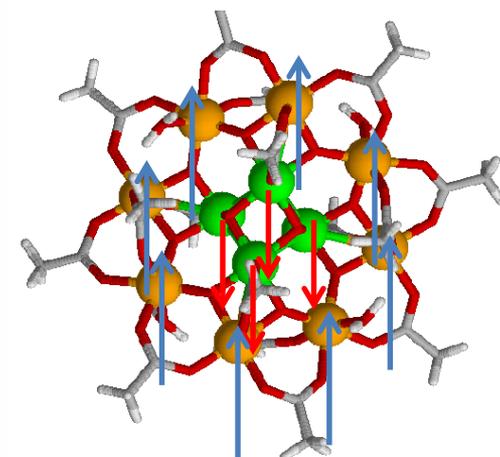

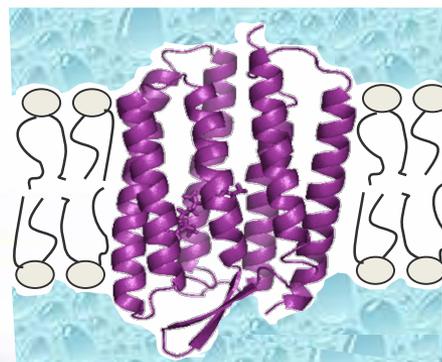

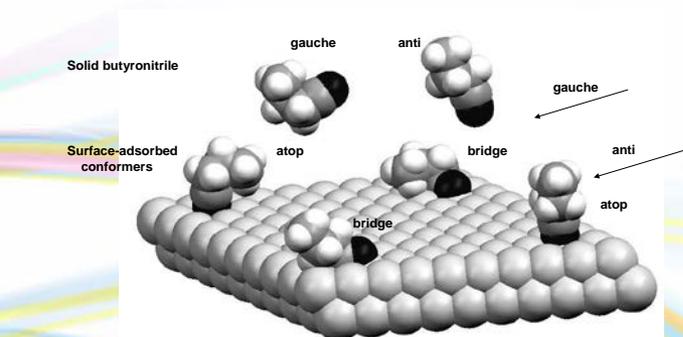

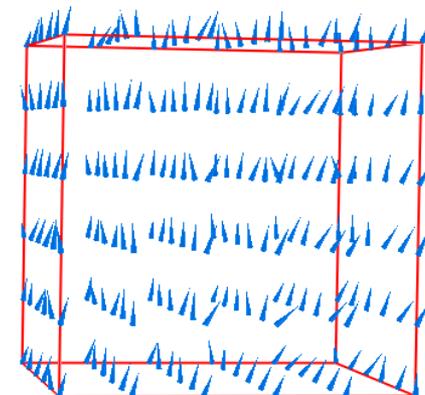

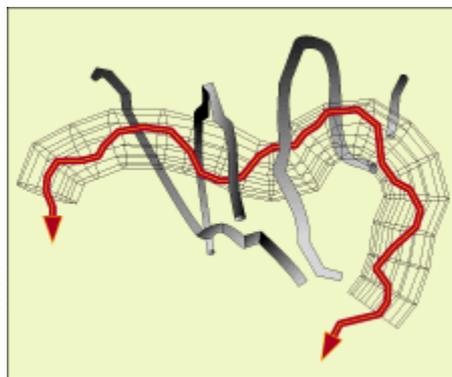

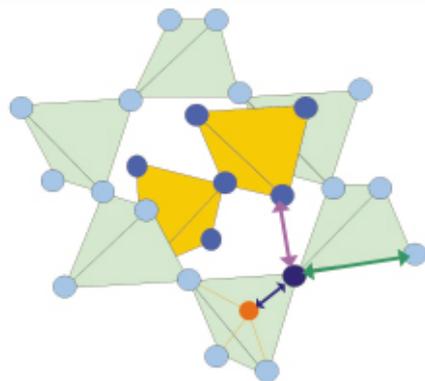

- Co/NiO is prototype exchange bias material – need to understand coupling at interface.

- PEEM at I06 with XMCD for (FM) Co L3 and XMLD for (AFM) Ni L2 shows orientation of the two types of moments at the interface is perpendicular – opposite of what was inferred from less precise measurements

# Higher resolution spectroscopy: atomic and molecular motion in materials

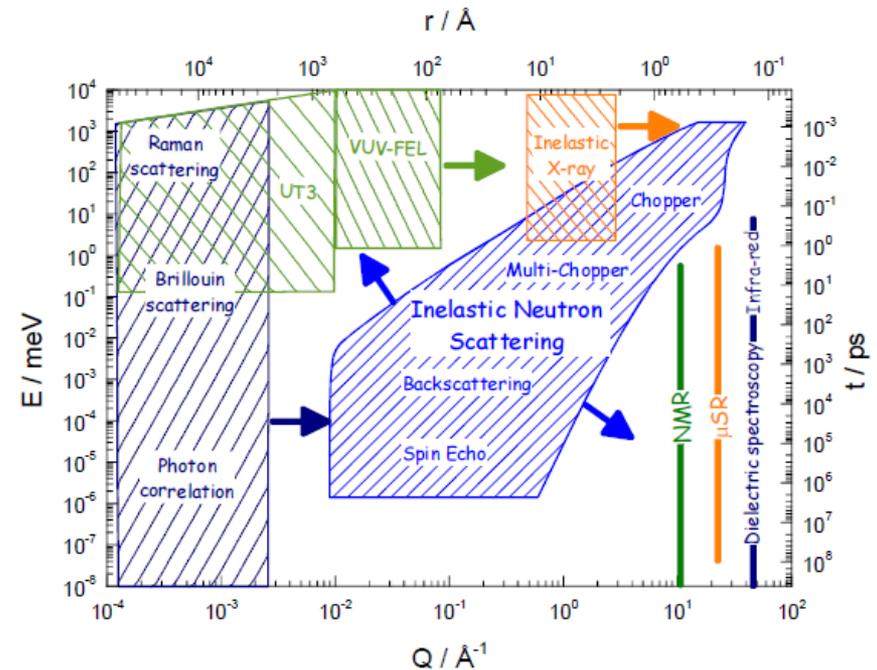

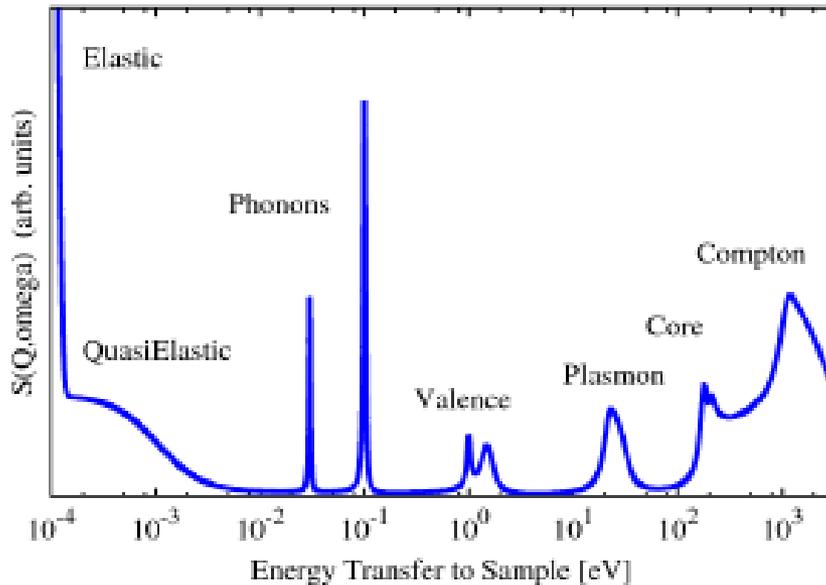

- Vibrations and magnetic excitations in molecules and solids are essential to key processes e.g. thermal conductivity and expansion, polymer processing and properties, biochemical processes, magnetic storage media, superconductors –

# Atomic and molecular motion in materials

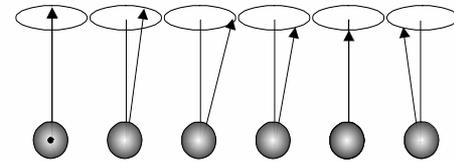

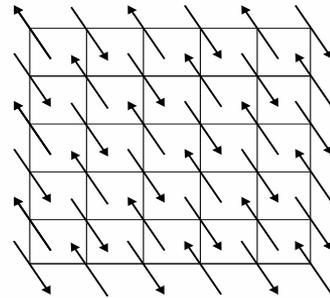

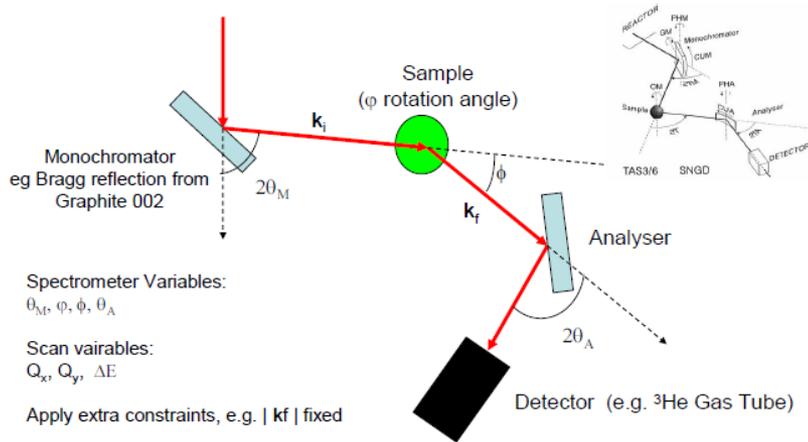

"When a crystal is irradiated with X-rays, the processes of photoelectric absorption and fluorescence are no doubt accompanied by absorption and emission of phonons. The energy changes involved are however so large compared with phonon energies that information about phonon spectrum of the crystal cannot be obtained in this way. The same is true for Compton scattering."<sup>1</sup> W.Cochran, 1966.

- Typically wish to measure vibrations and magnetic excitations in the range 1-100 meV as a function of  $q$  ( $1/\lambda$ ) so the wavelength of the neutrons or X-rays should typically be of the order of 1-2 Å (0.1-0.2 nm) [ $Q$  – measured momentum transfer;  $q$  – wavevector of the excitation]
- 1 Å corresponds to 12.4 keV for X-rays and 81.8 meV for neutrons so instrumental resolution is ***much*** more challenging for X-rays (10meV:  $\Delta E/E \cong 10^{-6}$  vs  $10^{-6}$  IXS vs INS)

# INS: experimental methods

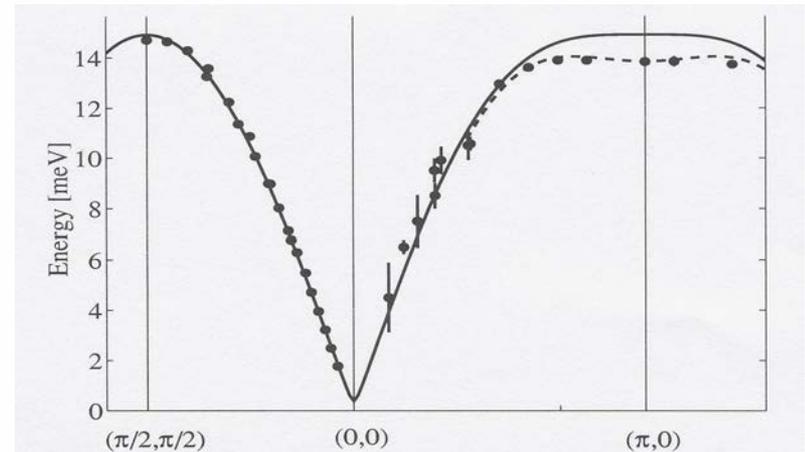

- Triple-axis spectrometer – very versatile means of measuring the change in energy of neutrons scattered by sample as a function of Q (point by point !)

$$Q = k_f - k_i \quad \hbar\omega = E_f - E_i \quad E_{f,i} = \hbar^2 k^2 / 2m_n$$

$\lambda = \infty$

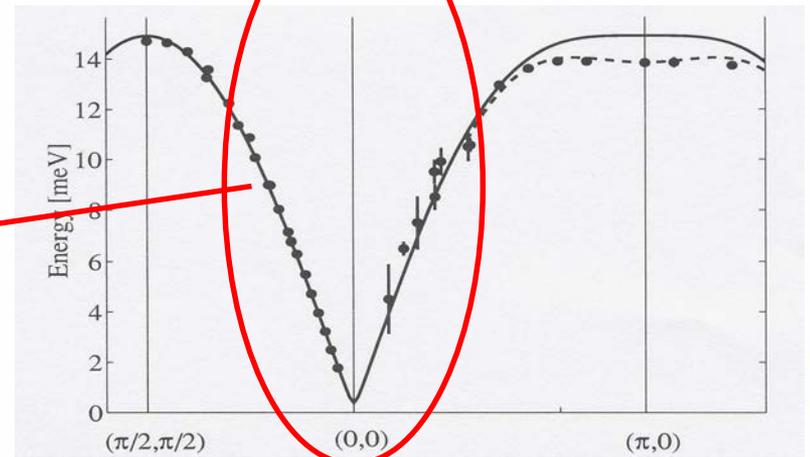

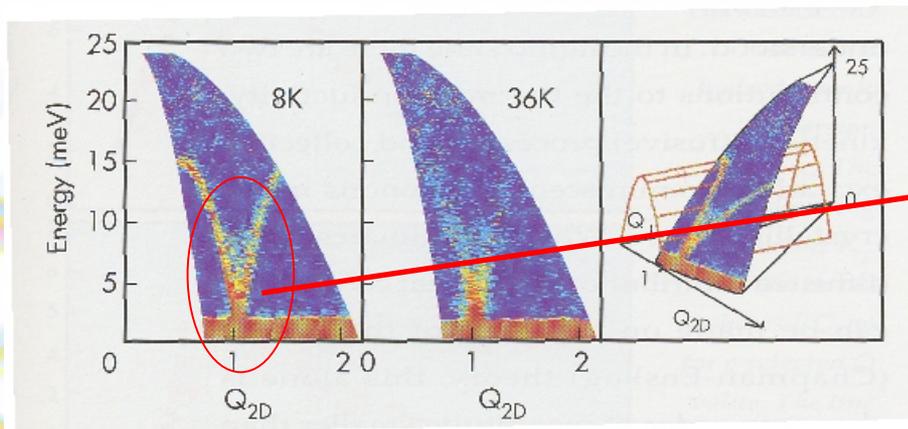

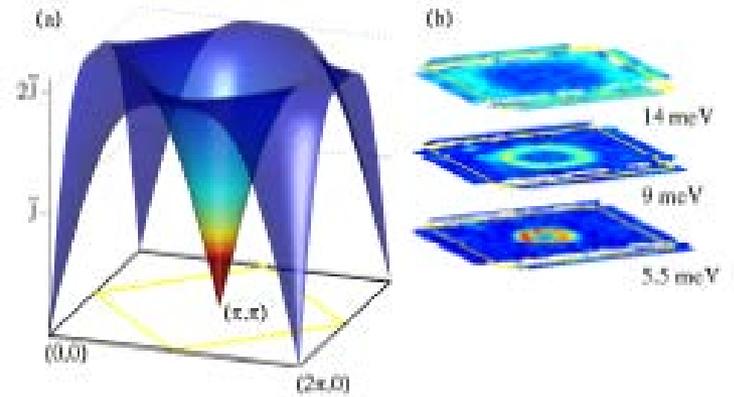

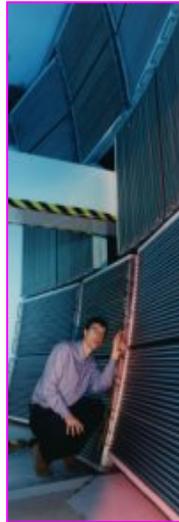

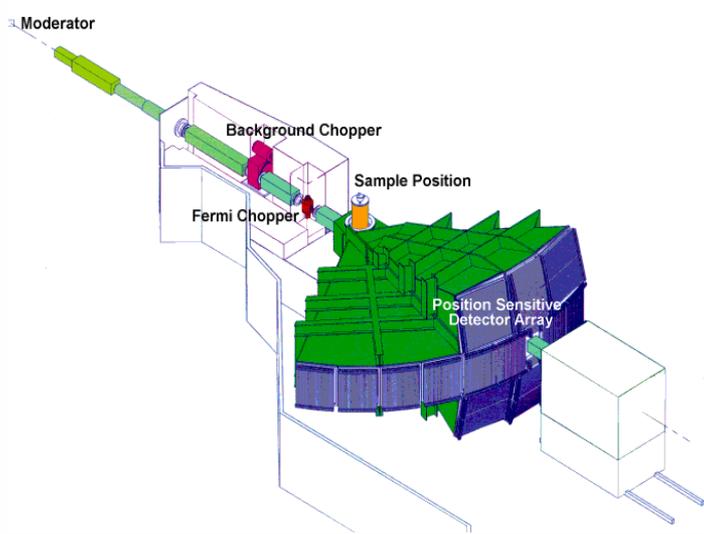

$\lambda = 2a$

$qa$

# INS: experimental methods

- With time-of-flight methods and large area detector, can map whole regions of Energy and Q in one fell swoop- often revealing unexpected features

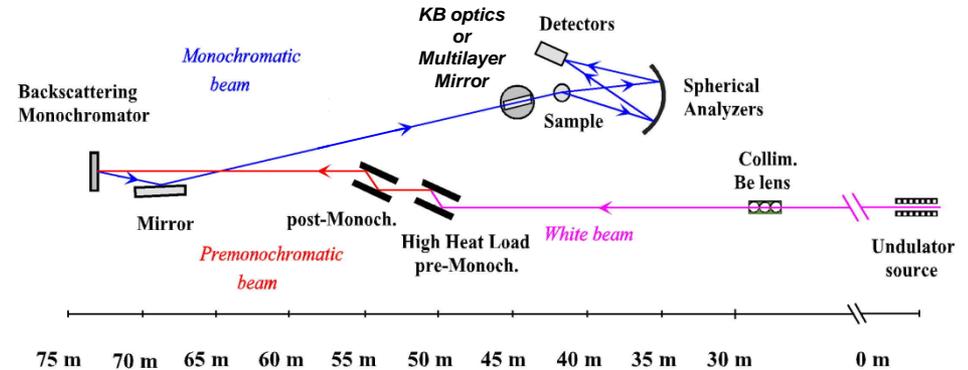

# IXS: experimental methods

- Far more challenging to resolve such excitations by inelastic X-ray scattering

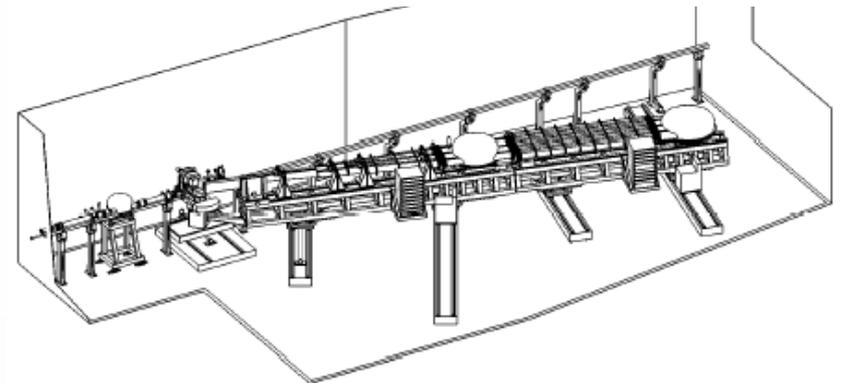

Optimise resolution with monochromator and analyser close to backscattering configurations:

$$d\lambda/\lambda = dE/E = \cot\theta d\theta \rightarrow 0 \text{ as } \theta \rightarrow \pi/2$$

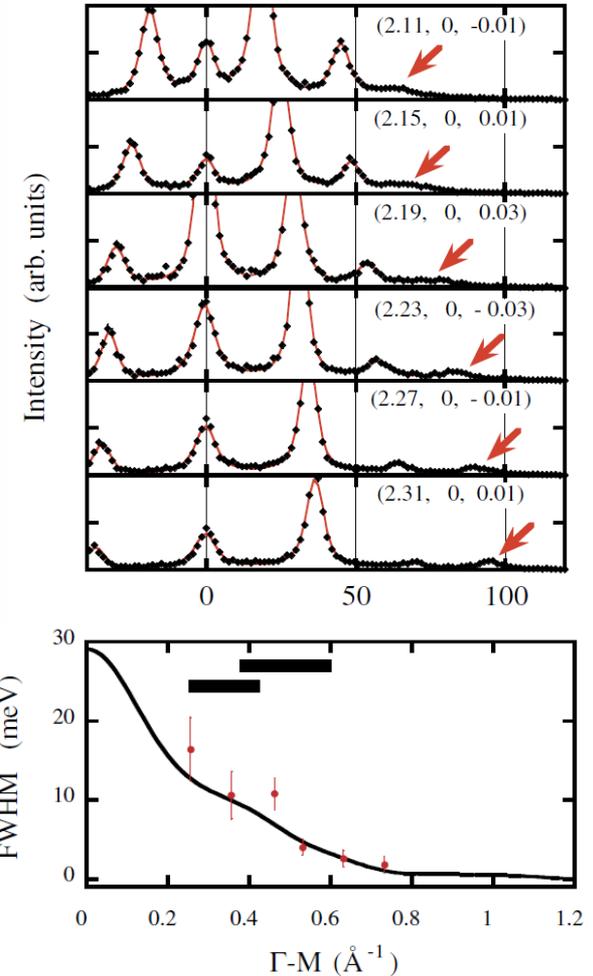

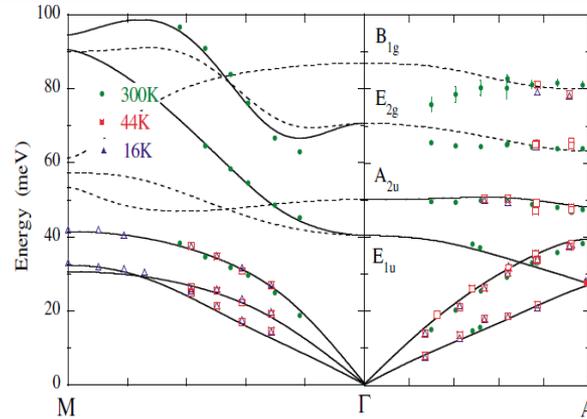

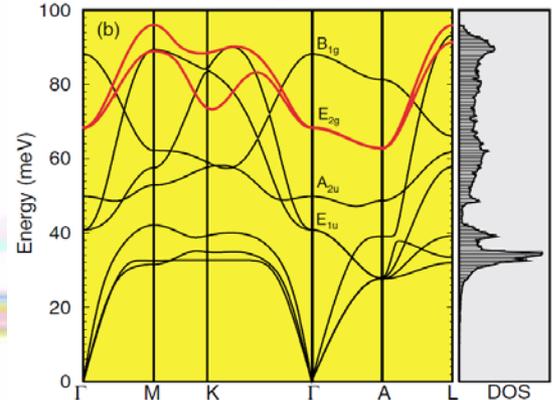

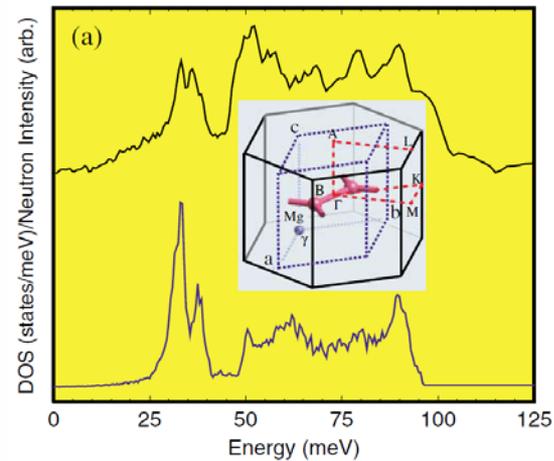

## 9- analyser crystal spectrometer

Reflection	Energy[ke V]	E [meV]	dE/E
Si(7,7,7)	13.840	5.30	$3.8 \cdot 10^{-7}$
Si(8,8,8)	15.817	4.40	$2.8 \cdot 10^{-7}$
Si(9,9,9)	17.794	2.20	$1.2 \cdot 10^{-7}$
Si(11,11,11)	21.747	0.83	$4.7 \cdot 10^{-8}$
Si(12,12,12)	23.725	0.73	$3.1 \cdot 10^{-8}$
Si(13,13,13)	25.704	0.50	$1.9 \cdot 10^{-8}$

# IXS: applications

- Role of phonons in superconductivity in  $\text{MgB}_2$  – DOS from lattice dynamics and neutron scattering measurements from powders then IXS on  $50 \times 70 \mu^2$  crystals

Yildirim et al, PRL 87 (2001) 37001  
Baron et al, PRL 92 (2004) 197004

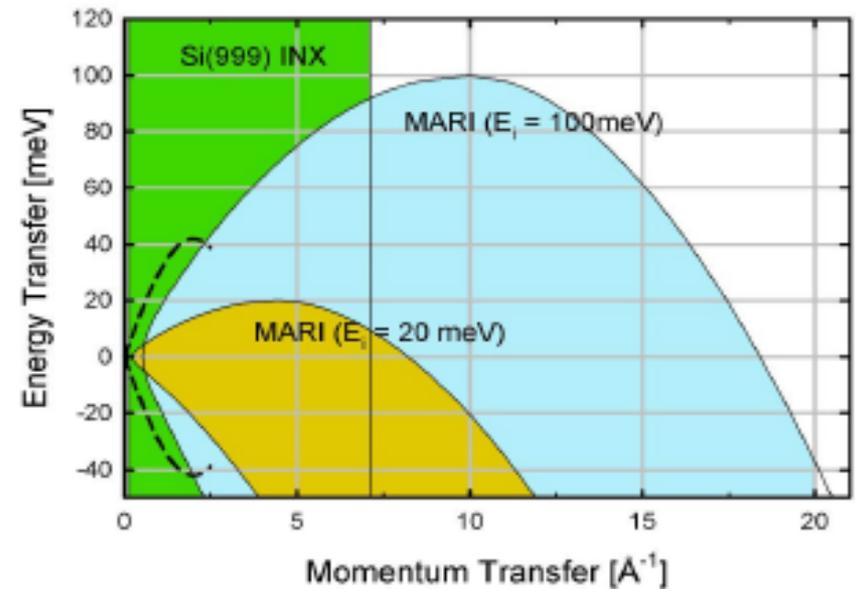

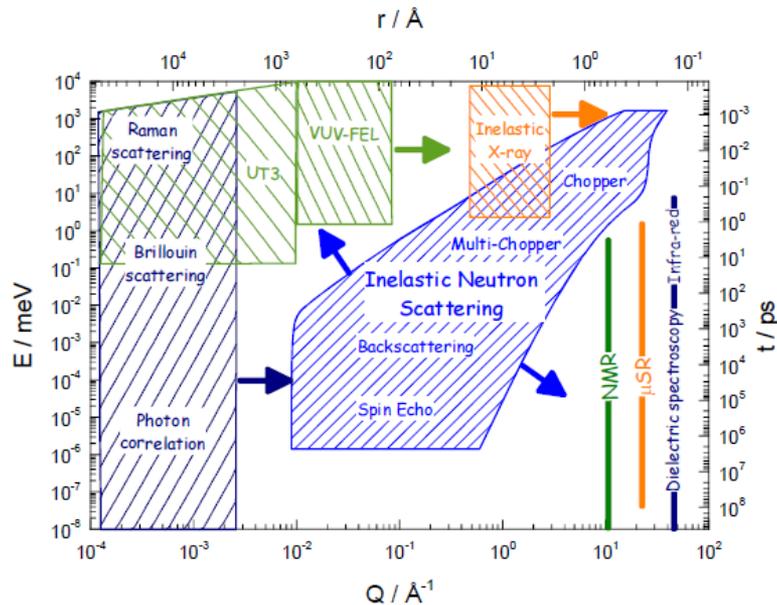

# IXS vs INS

## Advantages of IXS

- Fine beams -  $\sim 10 \mu\text{m}$  - work with very small samples
- Resolution is independent of energy transfer as  $\Delta E$  and  $Q$  are decoupled (below)
- Open up new kinematical window in  $\Delta E$ ,  $Q$  at small  $Q$  and high  $\Delta E$  – useful for disordered systems
- No incoherent scattering

## Disadvantages of IXS

- Very challenging instrumentation to achieve resolution  $\Delta E/E \sim 10^{-7}$
- Cross-section dominated by photoelectric absorption - less sensitive to light atoms
- Resolution more complex than for neutrons (non Gaussian)

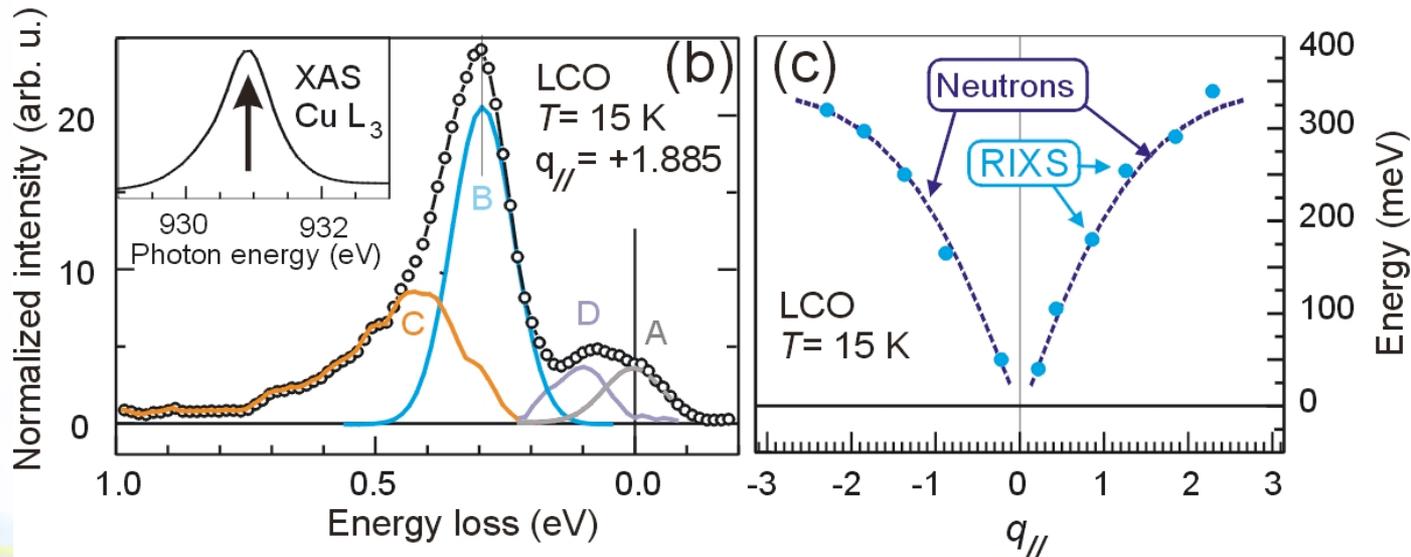

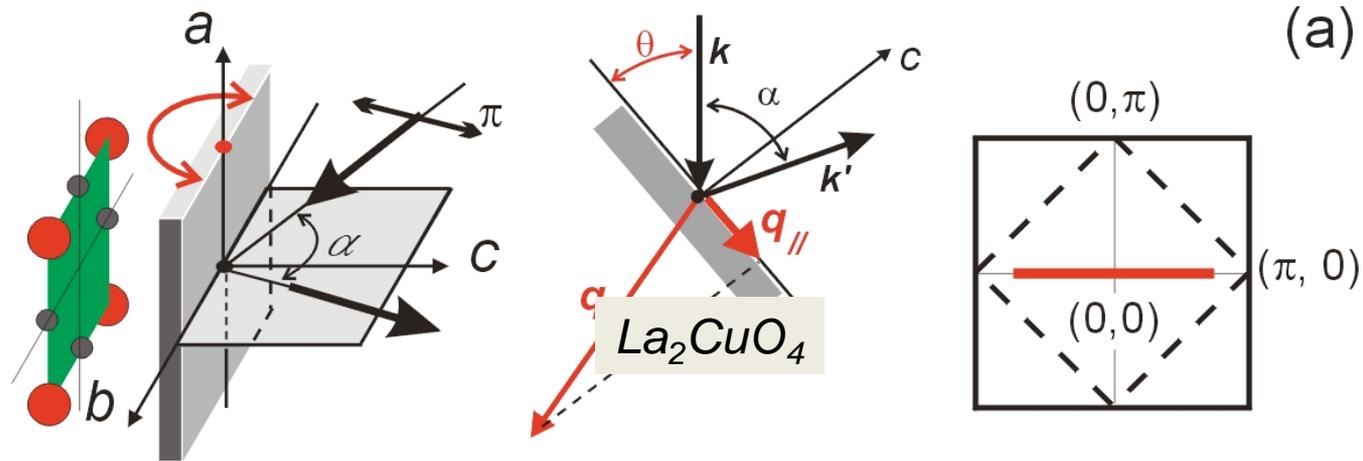

# IXS + R → RIXS: a complementary method to neutrons for studying magnetic excitations

High sensitivity of soft x-rays allows study of small sample volumes.

Tune to specific transition – element and orbital selective

***La<sub>2</sub>CuO<sub>4</sub>***
