

# **Polarized neutron scattering**

Polarized neutrons can be used to enhance (nearly) any neutron scattering experiment, either by providing additional information (this lecture), or improving the resolution or range using Larmor precession (A. Faraone)

#### Overview

- Principles of polarized neutron scattering
  - What is a polarized neutron beam?
  - How do polarized neutrons interact with matter?
  - What extra information can be gained by using polarized neutrons?
- Practical polarized neutron scattering
  - Polarized devices: polarizers/analyzers, flippers, and guide field
- Advanced applications of polarization analysis
  - Magnetic diffraction and diffuse scattering
  - SANS, reflectometry spectroscopy

## Spin angular momentum

Neutrons possess an inherent magnetic moment related to their spin-angular momentum S = 1/2

The **spin** has three components -x, y, and z. In a magnetic field, only the component along the field, conventionally z, is well defined.

#### Vector and Scalar Polarization

In a magnetic field, the polarization of a beam is a vector pointing in the direction of the field, with the length of the vector defined as the **scalar polarization**:

$$P = \frac{N_{+} - N_{-}}{N_{+} + N_{-}} \quad \text{or} \quad P = \frac{F - 1}{F + 1}; \quad F = \frac{N_{+}}{N_{-}}$$

Where F is the **flipping ratio**, a frequently measured experimental quantity.

To determine the polarisation of a beam, we insert a device that selects either  $\uparrow$  or  $\downarrow$  from the beam (*e.g.* another SG apparatus). This is called **polarization analysis**.

N = 3000  
A+ N<sub>+</sub> = 2100  

$$P = \frac{1200}{3000} = 40\%; F = \frac{7}{3}$$

### Polarized neutron scattering

Most samples also contain magnetic moments, originating either from nuclei or the electrons — **magnetism**.

The **scattered polarization** and **cross section** (intensity) depends on the relative orientation of the beam polarization and the magnetic moments in the sample.

➤ Analyzing the scattered beam can provide us with this information!

## Spin-flip and non-spin-flip scattering

In most cases, it is sufficient to analyse the scattered polarization along the same direction as the incident. This is called **longitudinal polarization analysis**.

We then only need to consider two types of process:

The neutron interacts with the nucleus via the **strong nuclear force** (Squires Ch. 9 and A. Boothroyd):

Consider a hydrocarbon polymer:

If we perform longitudinal polarization analysis, we can separate the contributions:

$$\left(\frac{d\sigma}{d\Omega}\right)_{++} = \left(\frac{d\sigma}{d\Omega}\right)_{\rm coh+II} + \frac{1}{3}\left(\frac{d\sigma}{d\Omega}\right)_{\rm inc} \qquad \left(\frac{d\sigma}{d\Omega}\right)_{+-} = \frac{2}{3}\left(\frac{d\sigma}{d\Omega}\right)_{\rm inc}$$

Consider a hydrocarbon polymer:

If we perform longitudinal polarization analysis, we can separate the contributions:

$$\left(\frac{d\sigma}{d\Omega}\right)_{\rm coh} = \left(\frac{d\sigma}{d\Omega}\right)_{++} - \frac{1}{2}\left(\frac{d\sigma}{d\Omega}\right)_{+-} \qquad \left(\frac{d\sigma}{d\Omega}\right)_{\rm inc}$$

3

2

 $d\sigma$ 

Magnetic scattering dominated by the **neutron-dipole** interaction (see N. Qureshi)

This means we now have to worry about the relative directions of the sample moment (magnetisation) M (often ordered), Q, and  $P_i$ . Complicated in general!

Let us consider the case where the electronic moments are disordered.

After averaging over the random direction of M, the magnetic elastic scattering cross section only depends on angle between the incident polarization  $P_i$  and Q:

$$\left(\frac{d\sigma}{d\Omega}\right)_{++} = \left(\frac{d\sigma}{d\Omega}\right)_{--} \propto 1 - (\hat{\mathbf{Q}} \cdot \hat{\mathbf{P}}_i)^2$$

$$\mathbf{P}_i \parallel \mathbf{Q} \qquad \mathbf{Z} \qquad \mathbf{P}_i \perp \mathbf{Q} \qquad \mathbf{Q} \qquad \mathbf{P}_i \perp \mathbf{Q} \qquad \mathbf{P}_i \perp \mathbf{Q} \qquad \mathbf{Q} \qquad \mathbf{P}_i \perp \mathbf{Q$$

Squires Ch. 9, p. 179

## Example 2: the $\parallel$ - $\perp$ method

Combining this with example 1, what if all three types of scattering are present?

Another case involves the electronic moments in the sample all being aligned

Bragg peak cross section now depends on the orientations of the magnetisation M,  $P_i$ , and Q. It also includes **both** nuclear and magnetic contributions. For M II  $P_i \perp Q$ :

Squires Ch. 9, p. 181

## Example 3: magnetic crystal polarizer

 $M \parallel P_i \perp Q - P_i + P_i M$ 

1.  $\mathbf{M} \perp \mathbf{Q}$  : measure all of M 2.  $\mathbf{P}_{\mathbf{i}} \parallel \mathbf{M} \perp$  : all scattering NSF  $+\mathbf{P}_{\mathbf{i}} \parallel \mathbf{M} : \left(\frac{d\sigma}{d\Omega}\right)_{++} \propto |F_N - F_M|^2 \sim 0.16$  barns  $-\mathbf{P}_{\mathbf{i}} \parallel \mathbf{M} : \left(\frac{d\sigma}{d\Omega}\right)_{--} \propto |F_N + F_M|^2 \sim 200$  barns Summary

#### Consequences

2

We can separate the components of the cross section (Examples 1,2)

We are also sensitive to the direction of magnetic moments

# Practical polarised neuton scattering

We've seen that we can polarise and analyse a beam with crystals like Cu<sub>2</sub>MnAl. However, these are normally fixed to accept only one state — need **flippers** 

We have also seen that it can be useful to rotate the polarisation versus Q and M – **guide field**. The guide field also preserves the polarisation between the elements.

## Polarized neutrons in practice

The first instrument of this kind was built by Moon, Riste, and Koehler in 1968

Moon, Riste, Koehler

#### 1. Magnetic crystal

## 2. Polarizing mirrors

#### 3. <sup>3</sup>He spin filter

<sup>3</sup>He (nuclear spin I = 1/2) has a spin-dependent absorption cross section:

Require high <sup>3</sup>He polarization for good neutron polarization  $\rightarrow$  lasers!

## Manipulating the polarization

After creating polarised beam, need to **guide/rotate** it and **flip** its direction. This is done using magnetic fields.

If the direction of the magnetic field changes, the polarization **Larmor precesses** around the new field direction.

The angle of the cone depends on the angle between the original field direction and the new field direction.

## Manipulating the polarization

Let us imagine we have a field changing at a rate  $\omega_B = d\theta_B/dt$ . We may then identify two cases by comparing this rate with the Larmor frequency and neutron velocity:

$$A = \frac{\omega_L}{\omega_B} = \frac{|\gamma|B}{v_n(d\theta_B/dx)}$$

#### Adiabatic (A > 10)

The spin follows the rotating field direction

#### Non-adiabatic (A < 0.1)

The spin immediately begins precessing about the new direction

Slow changes  $\rightarrow$  field rotation. Fast changes  $\rightarrow$  precession/flipping

Guide/rotating field is typically constructed using either permanent magnets or electromagnets:

## Non-adiabatic spin flippers

Meissner screen (Nb or YBCO)

2

Alternatively, we can use Larmor precession combined with non-adiabatic trans.

Mezei

- $\mathbf{B}_{tot} = \left(B_0 + \frac{\omega}{\gamma}\right)\hat{z} + B_1\hat{x}$
- 1. Non-adiabatic transition
- 2. Half a precession ( $\pi$ )
- 3. Non-adiabatic transition

- 1. Reversal of  $B_{tot}$  with RF field
- 2. Non-adiabatic transition

## Example instrument: D7, ILL

## Advanced polarised neutron scattering: Generalising polarisation analysis

**Science & Technology** Facilities Council

Reminder: rules of polarised neutron scattering

#### **Nuclear**

The nuclear coherent and isotope incoherent scattering is entirely NSF

The spin incoherent scattering is 1/3 NSF and 2/3 SF

#### Magnetic

3

2

) The components of the sample magnetisation perpendicular to  $\mathbf{Q}$  and...

- ... parallel to  $P_i$ : NSF
- ... perpendicular to  $P_i$ : SF

## 2D XYZ polarization analysis

In the case where we have a 2D detector, like in a powder diffractometer (*e.g.* D7), it is no longer possible to align  $\mathbf{Q}$  and  $\mathbf{P}_i$  for every detector. However:

 $(d\sigma/d\Omega)_{NSF}$  :  $(d\sigma/d\Omega)_{SF}$ 

## Examples: 2D XYZ PA

This technique can be used to separate very small signals in magnetically disordered powders (scatter like paramagnets):

#### **Frustrated magnets**

Clark et. al.

#### **Magnetic semiconductors**

Lancon et. al.

#### XYZ LPA: Magnetic single crystals

If the scattering is not paramagnetic-like, we're back to having to consider the directions of Q, M, and  $P_i$ . This is usually the case for single crystals.

Other complications we may encounter are the presence of **nuclear-magnetic interference** (Example 3), and **chiral scattering** for non-collinear structures:

If we can set  $\mathbf{x} \parallel \mathbf{Q}$ , and if we use two flippers, it is still possible (in most cases) to separate all of the components (see Blume, Ressouche for the maths).

#### Example: non-collinear structure

In the multiferroic  $Ni_3V_2O_8$ , we can select handedness by applying an electric field:

## Spherical polarimetry

In some cases, crystal symmetry means that different magnetic structures look identical in LPA. This is a result of the projection onto the  $P_i$  (field) direction:

In this case, LPA is insufficient, and we need to measure all components of the scattered polarization. This is achieved by performing **spherical polarimetry** 

$$\begin{array}{c}
\mathsf{M}_{\perp} & \mathsf{P}_{\mathsf{f},\mathsf{z}} \\
\mathsf{P}_{\mathsf{f},\mathsf{z}} & \longrightarrow \begin{pmatrix} P_{f,x} \\ P_{f,y} \\ P_{f,z} \end{pmatrix} = \begin{pmatrix} P_{xx} & P_{xy} & P_{xz} \\ P_{yx} & P_{yy} & P_{yz} \\ P_{zx} & P_{zy} & P_{zz} \end{pmatrix} \begin{pmatrix} P_{i,x} \\ P_{i,y} \\ P_{i,z} \end{pmatrix}$$

In spherical polarimetry, projection avoided by placing sample in zero field, and carefully controlling  $P_i$  and  $P_f$  with fields and flippers (see Brown, Forsyth, Tasset).

## Advanced polarized neutron scattering: Beyond (magnetic) diffraction

## **Example: Inelastic scattering**

One of the most promising future applications is inelastic polarised neutron scattering on wide-angle inelastic spectrometers.

#### D<sub>2</sub>O (LET, ISIS)

Polarized neutrons allow for the separation of collective  $S_{coh}(Q, E)$  and singleparticle dynamics  $S_{inc}(Q, E)$ . This has resulted in a revision of the model for the dynamics in water.

Arbe et. al.

## Conclusion

- Polarized neutron beams interact with magnetic moments (both nuclear and electronic) in samples. The scattered polarization and cross section depends on the type of scattering process (nuclear coherent, spin incoherent, or magnetic).
- Polarized neutron beams can therefore be used to:
  - Separate cross section components
  - Determine magnetic moment orientations
  - Access parts of the cross section inaccessible to unpolarised neutrons
- Polarized neutron beams can also be used to improve the resolution of neutron scattering (A. Faraone)
